## 

You already know that building APIs with Spring Boot is incredibly easy. But, your API isn't complete without a UI, right? Well, building UIs with Ionic is an open source framework designed to help you build mobile applications with web technologies. It started out as a framework based on AngularJS. Ionic 3.0 was recently released, with support for Angular 4, TypeScript 2.2, and lazy loading. When developing an Ionic app, you'll use Angular and have access to native APIs via Ionic Native and Apache Cordova. This means you can develop slick-looking UIs using the technologies you know and love: HTML, CSS, and TypeScript. This tutorial will show you how to build a Spring Boot API and an Ionic app, and then how to deploy the finished product to your iOS or Android-based mobile device. Together, these technologies provide an excellent developer experience, with hot reloading so you see immediate feedback whenever you change files. Prerequisites: Java 8 and Node.js installed. Create a New Spring Boot Project To begin, create a directory on your hard drive called spring Boot API in Bootiful Development with Spring Boot with Angular. Rather than covering that again, you can clone the existing project and copy the server directory into spring-boot-ionic-example/. This project contains a beers API that allows you to CRUD a list of beer names. It also contains a /good-beers endpoint that filters out less-than-great beers. A BeerCommandLineRunner { private final BeerRepository; public BeerCommandLineRunner { private final BeerRepository; } @Override public void run(String... strings) throws Exception { // Top beers from Stream.of("Kentucky Brunch Brand Stout", "Good Morning", "Very Hazy", "King Julius", "Budweiser", "Coors Light", "PBR").forEach(name -> repository.save(new Beer(name)) ); repository.findAll().forEach(System.out::println); } The BeerRepository interface is decorated with @RepositoryRestResource to expose CRUD endpoints for the Beer entity. @RepositoryRestResource interface BeerRepository {} The last piece of the API is the BeerController that exposes /good-beers and specifies cross-origin resource sharing (CORS) settings. @RestController public class BeerController { private BeerRepository repository; public BeerController(BeerRepository, public Collection goodBeers() { return repository, indAll().stream() .filter(this::isGreat) .collect(Collectors.toList()); } private boolean isGreat(Beer beer) { return repository.findAll().stream() .filter(this::isGreat) .collect(Collectors.toList()); } !beer.getName().equals("Budweiser") && !beer.getName().equals("Coors Light") && !beer.getName().equals("PBR"); } You should be able to start the server application by running it in your favorite IDE or from the command line using mvn spring-boot:run. You'll want to do this from the server directory. If you don't have Maven installed, you can use the Maven wrapper that's included in the project (./mvnw spring-boot:run). After the app has started, navigate to . You should see the list of good beers in your API, you'll first need to install lonic CLI and Cordova: npm install -g ionic cordova The Ionic CLI is a command-line tool that significantly reduces the time it takes to develop an Ionic app. It's like a Swiss Army Knife: It brings together a bunch of miscellaneous tools under a single interface. The CLI contains a number of useful commands for Ionic development, such as start, build, generate, serve, and run. After installation completes, cd into springboot-ionic-example and create a new application using the following command: You will be prompted to select a starter project and optionally integrate with Cordova to target native iOS and Android. For the purposes of this tutorial, choose the tabs starter project and answer Yes to Cordova. cd ionic-beer ionic serve This will open your default browser on . You can click through the tabbed interface to see the default structure of the app. Open the ionic-beer project in your preferred IDEA to start creating your UI. I recommend using Intellij IDEA because it has good TypeScript support and can auto-import classes just like it does for Java project. Create a Good Beers UI Run ionic generate page beer to create a component and a template to display the list of good beers. This creates a number of files in src/pages/beer: beer.html beer.module.ts and add BeerPageModule to the imports list in app.module.ts. import { BeerPageModule } from '../pages/beer/beer.module'; @NgModule({ ... imports: [BrowserModule, IonicModule.forRoot(MyApp), BeerPageModule ], ... }) Create src/providers/beer-service.ts to hold a BeerService that fetches the beer list from the Spring Boot API. Populate it with constants for the API path and add a getGoodBeers() method. import { Injectable } from '@angular/core'; import { Observable } from 'rxjs'; import { HttpClient } from '@angular/common/http'; @Injectable() export class BeerService { public API = ' '; public BEER API = this.API + '/good-beers'); } } Replace the HTML in src/pages/beer/beer.html to show the list of beers. Good Beers {{beer.name}} Modify src/pages/beer.beer.module.ts to import BeerService and add it as a provider. You could add it as a provider in each component, but adding it in the module allows all components to use it. import { BeerService } from '.../providers/beer-service'; @NgModule({ ... providers: [ BeerService ] }) Update src/pages/beer/beer.ts to import BeerService and add it as a dependency in the constructor. Call the getGoodBeers() method in the ionViewDidLoad() lifecycle method. import { IonicPage, NavController, NavParams } from 'ionic-angular'; import { BeerService } from '.../../providers/beer-service' @IonicPage() @Component({ selector: 'page-beer', templateUrl: 'beer.html' }) export class BeerPage { private beers: Array; constructor(public navCtrl: NavController, public beers; }) } To expose this page on the tab bar, modify src/pages/tabs/tabs.ts and re-arrange things so BeerPage is second in the list. import { Component } from '../about/about'; import { ContactPage } from '../about/about'; import { ContactPage } from '../about/about'; import { BeerPage } from '../about/about'; import { ContactPage } from '../about/about'; import } from '../about/about'; import { ContactPage } from '../about/about'; import } from '../about/about'; import } from '../about from '../a templateUrl: 'tabs.html' }) export class TabsPage { tab1Root = HomePage; tab2Root = BeerPage; tab3Root = AboutPage; tab4Root = ContactPage; tab3Root = AboutPage; tab3Root = ContactPage; tab3Root = C src/providers/giphy-service.ts with code that searches Giphy's API. import { Injectable } from '@angular/core'; import { HttpClient } from '@angular/core'; import { HttpClient } from '@angular/core'; import 'rxjs/add/operator/map'; @Injectable() // export class GiphyService { giphyApi = ' constructor(public http: HttpClient) { } get(searchTerm) { const apiLink = this.giphyApi - t searchTerm; return this.http.get(apiLink).map((response: any) => { if (response.data.length > 0) { return response.data[0].images.original.url; } else { return '; // dancing cat for 404 } }); } } Update beer.module.ts to import GiphyService and include it as a provider. import { GiphyService } from '../../providers/giphy-service'; @NgModule({ ... providers: [BeerService, GiphyService] }) Modify beer.ts to import { GiphyService and set a giphyUrl on each beer. import { Component } from '.../../providers/giphy-service'; import { GiphyService } from '.../../providers/giphy-service'; import { SighyService } from '.../../provide @IonicPage() @Component({ selector: 'page-beer', templateUrl: 'beer.html' }) export class BeerPage { private beers: Array; constructor(public navCtrl: NavController, public beers) { } ionViewDidLoad() { this.beerService: GiphyService: Giphy this.beers = beers; for (const beer of this.beers) { this.giphyService.get(beer.name).subscribe(url => { beer.giphyUrl = url }); } } } Update beer.html to display the image retrieved: { beer.name } Start the Spring Boot app in one terminal window and run ionic serve in another. Open in your browser. Click on the Beer icon, and you'll likely see an error in your browser. Error: Uncaught (in promise): Error: StaticInjectorError[HttpClient]: NullInjectorError: No provider for HttpClient]: NullInjectorError: No provider for HttpClient]: StaticInjectorError[HttpClient]: NullInjectorError: No provider for HttpClient]: NullInjectorError[HttpClient]: NullInjectorError: No provider for HttpClient]: NullInjectorError: No provider for HttpClient]: NullInjectorError[HttpClient]: NullInjectorError: No provider for HttpClient]: NullInjectorError[HttpClient]: NullInjectorError: No provider for HttpClient]: NullInjectorError[HttpClient]: NullInjectorError[HttpClient]: NullInjectorError[HttpClient]: NullInjectorError[HttpClient]: NullInjectorError[HttpClient]: NullInjectorError: No provider for HttpClient]: NullInjectorError[HttpClient]: NullError[HttpClient]: NullError[HttpClient]: NullError[HttpClient]: NullError[HttpClient]: NullError[HttpClie to solve this issue. import { HttpClientModule } from '@angular/common/http'; @NgModule({ ... imports: [ BrowserModule, HttpClientModule, JonicModule, HttpClientModule, JonicModule, HttpClientModule ], After making this change, you'll likely see the following error in your browser's console. XMLHttpRequest cannot load . No 'Access-Control-Allow-Origin' header is present on the requested resource. Origin ' is therefore not allowed access. The response had HTTP status code 401. To fix this, open your Spring Boot application's BeerController.java class and change its @CrossOrigin annotation to allow and . This enables cross-origin resource sharing (CORS) from both the browser and the mobile client (is used by iOS Simulator). @CrossOrigin(origins = {" "," "}) public Collection goodBeers() { Recompile this class, and DevTools should restart the application. If everything works as expected, you should restart the application are below in your browser. Change the header in beer.html to have a button that opens a modal to add a new beer. Good Beers In this same file, change to have a click handler for opening the modal for the current item. Add ModalController, NavController, NavController, NavController, NavParams } from 'ionic-angular'; export class BeerPage { private beers: Array; constructor(public navCtrl: NavController, public navParams: NavParams: NavParams; public beerService: BeerService; public giphyService; public modalCtrl: ModalController) { } // ionViewDidLoad() openModal(beerId) { let modal = this.modalCtrl.create(BeerModalPage, beerId); modal.present(); // refresh data after modal dismissed modal.onDidDismiss(() => this.ionViewDidLoad()) } This won't compile because BeerModalPage doesn't exist. Create beer-modal.ts in the same directory. This page will retrieve the beer from the beerId that's passed in. It will render the name, allow editing, and show the Giphy image found for the name. import { BeerService } from '.../../providers/beer-service'; import { Component, ViewChild } from '@angular/core'; import { NavParams, ViewController, ToastController, ToastController, ToastController, ToastController, SecondalPage { @ViewChild('name') } from '@angular/forms'; @Component({ templateUrl: './beer-modal.html' }) export class BeerModalPage { @ViewChild('name') } name; beer: any = {}; error: any; constructor(public beerService: BeerService: giphyService: GiphyService: GiphyService: GiphyService: any) => { this.beer = {}; error: any; constructor(public beerService: giphyService: GiphySe beer; this.beer.href = beer. links.self.href; this.giphyService.get(beer.name).subscribe(url => beer.giphyUrl = url); }; } dismiss() { this.viewCtrl.dismiss(); } save(form).subscribe(result => { let toast = this.toastCtrl.create({ message: 'Beer ''' + form.name + ''' + ((update) + (update) + (up ? 'updated' : 'added') + '.', duration: 2000 }); toast.present(); this.dismiss(); }, error = error) } ionViewDidLoad() { setTimeout(() => { this.name.setFocus(); },150); } } Add the import for BeerModalPage to beer.ts, then create src/pages/beer/beer-modal.html as a template for this page. { {beer ? 'Beer Details' : 'Add Beer'} } Cancel {{error}} Save You'll also need to modify beer-service.ts to have get() and save() methods. get(id: string) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save(beer: any): Observable; if (beer['href']) { return this.http.get(this.BEER API + '/' + id); } save( Observable.throw(error)); } At this point, if you try to add or edit a beer name, you'll likely see an error in your browser's console. Uncaught (in promise): Error: No component factory found for BeerModalPage. Did you add it to @NgModule.entryComponents? To fix this problem, add BeerModalPage to the declarations and entryComponent lists in beer.module.ts. import { BeerModalPage } from './beer-modal'; @NgModule({ declarations: [ BeerPage, BeerModalPage ], ... entryComponents: [ BeerModalPage ], ... entry matches the one in BeerController. @RepositoryRestResource @CrossOrigin(origins = {" "," "}) Re-compile and now everything should work as expected. For example, below is a screenshot that shows I added a new beer and what it looks like when editing it. Add Swipe to Delete To add swipe-to-delete functionality on the list of beers, open beer.html and make it so wraps and contains the \*ngFor. Add a delete button using . {{beer.semove(beer.id).subscribe(response => { for (let i = 0; i < this.beers.length; i++) { if (this.beers.splice(i, 1); let toast = this.toastCtrl.create({ message: 'Beer ''' + beer.name + '" deleted.', duration: 2000, position: 'top' }); toast.present(); } }); } Add and import ToastController, public navCtrl: NavController, pub ModalController, public toastCtrl: ToastController) { } You'll also need to modify beer-service.ts to have a remove() method. remove(id: string) { return this.http.delete(this.BEER API + '/' + id); } After making these additions, you should be able to delete beer names. To emulate a left swipe in your browser, click on the item and drag it to the left. PWAs with Ionic Ionic Ships with support for creating progressive web apps (PWAs). If you'd like to learn more about what PWAs are, see Navigating the World of Progressive Web Apps with Ionic 2. This blog post is still relevant for Ionic 3. If you run the Lighthouse Chrome extension on this application, you'll likely get a mediocre score in the 40s. To register a service worker, and improve the app's score, uncomment the following block in src/index.html. After making this change, the score should improve. In my tests, it increased to 73/100. The remaining issues were: Does not redirect HTTP traffic to HTTPS Page load is not fast enough on 3G Has a tag with width or initial-scale To fix the first issue, add the following HTML in src/index.html, just after the tag's content attribute. Deploy to a Mobile Device It's pretty cool that you're able to develop mobile apps with Ionic in your browser. However, it's nice to see the fruits of your labor and see how awesome your application will look on different devices you can run ionic serve --lab. The --lab flag opens a page in your browser that lets you see how your application will look on different devices you can run ionic serve --lab. devices. iOS To emulate or deploy to an iOS device, you'll need a Mac and a fresh installation of Xcode. If you'd like to build iOS apps on Windows, Ionic offers an Ionic Package service. Make sure to open Xcode to complete the installation. Then run ionic cordova emulate ios to open your app in Simulator. TIP: The biggest problem I found when running the app in Simulator was that it was difficult to get the keyboard to popup. To workaround this, I used Hardware > Keyboard > Toggle Software Keyboard > Toggle Software Keyboard to popup. To workaround this, I used Hardware > Keyboard > Toggle Software Keyboard to popup. use your computer's IP address in beer.service.ts (if you're on the same wireless network). To deploy to Cloud Foundry, copy this deploy.sh script to your apps to be named ionic-beer and server. If you don't have a Cloud Foundry account, you'll need to create one. Then install its command line tools (and login) for this script to work. brew tap cloudfoundry/tap && brew install cf-cli cf login -a api.run.pivotal.io After logging into Cloud Foundry, you should be able to run./deploy.sh. This script will deploy the server and modify beer.service.ts to point to it. It will also try to deploy to your phone, so you may need to complete the steps below before it will work. To deploy the app to an iPhone, start by plugging it into your computer. Then run the following commands to install ios-deploy/ios-sim, build the app, and run it on your device. Select your phone as the target in Xcode and click the play button to run your app. The first time you do this, Xcode may spin for a while with a "Processing symbol files" message at the top. NOTE: If you run into code signing issues, see Ionic's deployment documentation to see how to solve. Once you've configured your phone, computer, and Apple ID to work, you should be able to open the app and see the beer list you created. Below is how it looks on my iPhone 7 Plus. Android Studio. As part of the install, it will show you where it installed the Android SDK. Set this path as an ANDROID\_HOME environment variable On a Mac, it should be ~/Library/Android/sdk/. If you've just installed Android Studio, make sure to open it to complete the installation. To deploy to the Android support and display an error if you don't have any AVD (Android Virtual Device) images. (node:9300) UnhandledPromiseRejectionWarning: CordovaError: No emulator images (avds) found. 1. Download desired System Image and install the HAXM device driver To create a new AVD, open Android Studio and navigate to Tools > Android > AVD Manager. Create a new Virtual Device and click Play. I chose a Pixel 2. After performing these steps, you should be able to run ionic cordova emulate android and see your app running in the AVD. Learn More about Ionic and Angular I hope you've enjoyed this tour of Ionic and Angular. I like how Ionic takes your web development skills up a notch and allows you to create mobile application created in this blog post on GitHub. If you encountered issues, please create an issue in GitHub or hit me up on Twitter @mraible. To learn more about Ionic and Angular, please see the following resources: Update: To learn how to add authentication (PWA), and your service worker and web app manifest are working swimmingly. You've even taken the time to deploy it to a server with HTTPS, and you're feeling pretty good about things. But wait, you don't have any way of knowing who your users are! Don't you want to provide them with an opportunity to authenticate and tell you who they are? Once you know who they are? Once you know who they are? app, and maybe even support your work! In this article, I'll show you how you can lock down a Spring Boot app, then use a modern authenticate and gain access to its APIs. Secure Your Spring Boot App You might've heard that Stormpath joined forces with Okta a few months ago (February 2017). Since the transition, we've been working hard to make the Stormpath SDKs work with Okta's April asp to log. Then I'll show you how you can use OIDC and Okta's April asp to log. in and get data from the Spring Boot app. I recently created a Spring Boot app that provides a list of good beers, based on a pre-populated list. It filters out less-than-great beers and displays them in an Angular UI that displays the first animated GIF (from Giphy) that matches the beer name. Let's get started! Rather than building Spring Boot and Angular applications from scratch, you can clone an existing GitHub project to get you going quickly. git clone If you'd prefer to build this application with Angular and Spring Boot. In this project's server/pom.xml file, you'll need to add the Okta Spring Boot starter as a dependency, and force Spring Security to use the latest version of Spring Security.oauth spring-security.oauth spring-security.o with Okta To begin, you'll need to create an Okta Developer account. This account is free forever and provides the complete Okta Identity Platform for up to 3 applications and 100 users. Head on over to Fill out the signup form, and click "Get Started" Within a few minutes, you'll get a confirmation email, follow the instructions in the email to finish setting up your account Log in to your Okta Developer account and navigate to Applications > Add Application. Click Single-Page App, click Next, and give the app a name you'll remember (e.g., "Angular PWA"). Change all instances of localhost: 8080 to localhost: 4200 and click Done. TIP: Add as a Logout redirect URI, so log out functionality works in your Angular app. Copy the client ID into your server/src/main/resources/application.properties file. While you're in there, add a okta.oauth2.issuer = https://{yourOktaDomain}/oauth2/default okta.oauth2.clientId={clientId} Update server/src/main/java/com/okta/developer/demo/DemoApplication.iava to enable it as a resource server. import org.springBootApplication.enableResourceServer; @EnableResourceServer; @EnableResourceServer Expires: 0 Pragma: no-cache Pragma: no-cache Pragma: no-cache Transfer-Encoding: chunked WWW-Authenticate: Bearer realm="api://default", error="unauthorized", error\_description="Full authenticate: Bearer realm="api://default", error\_description="Full authenticate: Bearer realm="api:/ "error description": "Full authentication is required to access this resource" } Authenticate with OpenID Connect Start the Angular application by running the following commands in your project's root directory. cd client npm install ng serve If you receive an error like the one below, disable the warning using the instructions provided, or just ignore

it. You can upgrade your dependencies in package.json, but there's no guarantee that this tutorial will still work!;) Your global Angular CLI version (1.6.7). The local Angular CLI version (1.6.7). The local Angular CLI version (1.6.7). see a cross-origin request error. Failed to load No 'Access-Control-Allow-Origin' header is present on the requested resource. Origin ' is therefore not allowed access. The response had HTTP status code 401. You can usually use a @CrossOrigin annotation to enable cross-origin resource sharing (CORS) on the server, but it won't work once you integrate Spring Security. To solve this issue, create a simpleCorsFilter bean in your DemoApplication; import org.springframework.boot.autoconfigure.SpringBootApplication; import org.springframework.boot.web.servlet.FilterRegistrationBean; import org.springframework.context.annotation.Bean; import org.springframework.core.Ordered; import org.springframework.web.cors.Configuration; import org.springframework.web.cors.ConfigurationSource; import org.springframework.web.filter.CorsFilter; import java.util.Collections; @EnableResourceServer @SpringBootApplication.run(Demo new UrlBasedCorsConfigurationSource(); CorsConfiguration(); config.setAllowedMethods(Collections.singletonList("\*")); config.setAllo FilterRegistrationBean bean = new FilterRegistrationBean(new CorsFilter(source)); bean.setOrder(Ordered.HIGHEST PRECEDENCE); return bean; } } You can remove the @CrossOrigin annotation from BeerController.java since it's no longer needed. Make sure to save the files you changed and restart your server. Install Manfred Steyer's project to add OAuth 2 and OpenID Connect support to your Angular client. npm install --save angular-oauth2-oidc Update client/src/app/app.component.ts to import { vour Okta application settings (replacing { clientId} and { yourOktaDomain} with the values from your "Angular PWA" OIDC app). import { JwksValidationHandler, OAuthService } from 'angular-oauth2-oidc'; ... constructor(private oauthService.clientId + '{clientId}'; this.oauthService.scope = 'openid profile email'; this.oauthService.oidc = true; this.oauthService.issuer = 'https://{yourOktaDomain}/oauth2/default'; this.oauthService.tokenValidationHandler = new JwksValidationHandler(); this.oauthService.loadDiscoveryDocumentAndTryLogin(); } ... Modify client/src/app/app.component.html to use instead of . Create client/src/app/home/home.component.ts and configure it to display Login and Logout buttons. import { Component } from '@angular/core'; import { OAuthService } from 'angular-oauth2-oidc'; @Component({ template: ` Welcome, { { givenName } ! Logout Beer List Login ` }) export class HomeComponent { constructor(private oauthService: OAuthService) { } login() { this.oauthService } interface ( from 'angular-oauth2-oidc'; @Component( from 'angular-oauth2-oidc'; this.oauthService.logOut(); } get givenName() { const claims: any = this.oauthService.getIdentityClaims(); if (!claims) { return null; } return claims.name; } } Modify client/src/app/shared/beer/beer.service.ts to read the access token from oauthService.and add an Authorization header. import { Injectable } from '@angular/core'; import { HttpClient HttpHeaders } from '@angular/common/http'; import { Observable } from 'rxjs/Observable } from 'rxjs/Observable } from 'angular-oauth2-oidc'; @Injectable() export { observable } from 'rxjs/Observable } from 'rxjs/Observable } from 'angular-oauth2-oidc'; @Injectable() export { observable } from 'rxjs/Observable } from getHeaders(): HttpHeaders(): HttpHeaders().set('Authorization', this.oauthService.authorizationHeader()); } } Create client/src/app/shared/auth/auth.guard.ts to navigate to the HomeComponent if the user is not authenticated. import { Injectable } from '@angular/core'; import { ActivatedRouteSnapshot, CanActivate, Router, Rou RouterStateSnapshot } from '@angular/router'; import { OAuthService } from 'angular-oauth2-oidc'; @Injectable() export class AuthGuard implements CanActivate { constructor(private oauthService; private router: Router) { } canActivate(route: ActivatedRouteSnapshot, state: RouterStateSnapshot): boolean { if (this.oauthService.hasValidIdToken()) { return true; } this.router.navigate(['/home']); return false; } } Add OAuthModule.forRoot() to the list of imports in client/src/app/app.module.ts, add HomeComponent in declarations, and lock the /beer-list route down with the AuthGuard. While you're there, add MatCardModule to the list of imports since HomeComponent uses components from this module. import { NoterModule } from 'angular-oauth2-oidc'; import { NoterModule } from 'angular/material'; const appRoutes: Routes = [ { path: 'beer-list', component: BeerListComponent, canActivate: [AuthGuard] }, { path: 'nedirectTo: 'home', pathMatch: 'full' }, { path: '\*\*', redirectTo: RouterModule.forRoot(appRoutes)], providers: [AuthGuard], bootstrap: [AppComponent] }) export class AppModule { } After making these changes, you should be able to run ng serve and see a welcome message like the one below. Click on Beer List to see data from your Spring Boot app. To add the "Home" link at the top (as shown in the screenshot above), modify client/src/app/beer-list/beer-list.component.html to include the following HTML. Home Beer List

## {{beer.name}}

If it works - great, now we can add auth with Okta! Authenticating with the Okta Auth SDK builds on top of Okta's Authenticating it using npm: npm install @okta/okta-auth-js --save Change HomeComponent to import OktaAuth and modify its template, so it has a sign-in form. import \* as OktaAuth from '@okta/okta-auth-js'; @Component({ template: `Welcome, { {givenName} }! Logout Beer List Login With Redirect Login Directly { {error} } Login `}) Update client/src/app/app.module.ts to import the dependencies required by Angular Material when working with forms. import { MatInputModule } from '@angular/platforms'; import { FormsModule, BrowserAnimationsModule, MatInputModule } from '@angular/forms'; import { BrowserAnimationsModule, BrowserAnimationsModule, MatInputModule } from '@angular/forms'; import { BrowserAnimationsModule, BrowserAnimationsModule } from '@angular/forms'; import { BrowserAnimationsModule, BrowserAnimationsModule } from '@angular/forms'; import { BrowserAnimationsModule } from '@angular/forms'; import HomeComponent should render as follows (after you've logged out and unchecked "Offline" in the Network tab): In HomeComponent, import Angular's ChangeDetectorRef, add it as a dependency in the constructor, and add local variables for the username and password fields. method uses the OktaAuth library to get a session token and exchange it for ID and access tokens. import { ChangeDetectorRef } from '@angular/core'; ... export class HomeComponent { private error: string; p ChangeDetectorRef) { } ... loginWithPassword() { this.oauthService.createAndSaveNonce().then(nonce => { const authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password) }).then((response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password) }).then((response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password) }).then((response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password) }).then((response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password: this.password) }).then((response.status === 'SUCCESS') { return authClient.signIn({ username: this.username, password) }).then((response.status === 'SUCCESS') { return auth authClient.token.getWithoutPrompt({ clientId: this.oauthService.clientId, responseType: ['id\_token', 'token'], scopes: ['openid', 'profile', 'email'], sessionToken; const accessToken; keyValuePair = `#id token=\${encodeURIComponent(idToken)}`; this.oauthService.tryLogin({ customHashFragment: keyValuePair, disableOAuth2StateCheck: true }).then(() => { // notify Angular that things have changed this.changeDetector.detectChanges(); }); }); } else { throw new Error('We cannot handle the ' + response.status + ' status'); } ).fail((error) => { console.error(error); this.error = error.message; }); } } You should be able to sign in with the form as one of your app's registered users. After logging in, you'll be able to sign in with the form as one of your app's registered users. After logging in, you'll be able to sign in with the form as one of your app's registered users. the coolest places on the internet - production! You'll need to modify the deploy.sh script in the root directory to replace in DemoApplication.java instead of BeerController.java, but that's about it. You can see the modified deploy.sh on GitHub. Copy the contents of this file on top of your existing deploy.sh. Install the Cloud Foundry CLI, then log into Pivotal Web Services. cf login -a api.run.pivotal.io Run ./deploy.sh and watch the magic happen! If you navigate to the client's URL after deploying, you'll see an error like the following in Chrome's console. Failed to load No 'Access-Control-Allow-Origin' header is present on the requested resource. Origin ' ' is therefore not allowed access. To fix this, modify the Trusted Origins on Okta (under API > Trusted Origins) to have your client's URL (e.g.). You'll also need to add this URL to the Login redirect URI and Logout redirect URI and Logout redirect URI and be able to load the beer list from your Spring Boot app. After I got everything deployed, I used Lighthouse to audit this application and found it received a perfect score. Huzzah! TIP: Joe Kutner, Java Languages Owner at Heroku, created a heroku.sh script you can find the source to audit this application to Heroku. code associated with this article on GitHub. If you find any bugs, please file an issue, or post your question to the Okta Developer Forums. Of course, you can always ping me on Twitter too. This article showed you how to add authentication with Okta to an Angular PWA with a Spring Boot API. You learned how to use OpenID Connect to get an access token and securely communicate with the backend. Finally, you saw how to deploy everything to Cloud Foundry and get a Lighthouse PWA score of 100. To learn more about PWAs, check out some recent tutorials I wrote: There's also a number of excellent resources by Google and Smashing Magazine: Page 3 Adopting a microservice architecture provides unique opportunities to add failover and resiliency to your systems, so your components can handle load spikes and errors gracefully. Microservices make change less expensive too. It can also be a good idea when you have a large team working on a single product. Your project can likely be broken up into components that can function independently of one another. Once components can function independently, they can be built, tested, and deployed independently. This gives an organization and its teams the agility to develop and deploy very quickly. In a previous article, I showed you how to convert the Angular app into a progressive web application that works offline. The Angular PWA is a good example of a resilient application because it still works when connectivity fails. Did you know you can develop similar resiliency in your API with Spring Boot, Spring Cloud, and a microservices architecture? This article shows you how to convert the previously created Spring Boot application to use microservices. You'll create a beer catalog service, an edge service, and allows them to communicate with one another. Before we dive into the code tutorial, I'd like to talk a bit about microservices, their history, and why you should (or should not) consider a microservices architecture for your next project. History of Microservices according to Wikipedia, the term "microservices" was a more appropriate name. Adrian Cockcroft, who was at Netflix at the time, described this architecture as "fine-grained SOA". Martin Fowler and James Lewis wrote an article titled simply Microservices on March 25, 2014. Years later, this is still considered the definitive article for microservices. Organizations and Conway's Law Technology has traditionally been organized into technology layers: UI team, database team, operations team. When teams are separated along these lines, even simple changes can lead to a cross-team project sucking down huge chunks of time and budget. A smart team will optimize around this and choose the lesser of two evils; forcing the logic into whichever application they have access to. This is an example of Conway's Law in action. Any organization that designs a system (defined broadly) will produce a design whose structure is a copy of the organization's communication structure. — Melvyn Conway, 1967 Microservices Architecture Philosophy of a microservices architecture is essentially equal to the Unix philosophy of "Do one thing and do it well". The characteristics of a microservices architecture are as follows: Componentization via services Smart endpoints and dumb pipes Decentralized data management Infrastructure automation Design for failure Evolutionary design Why Microservices? For most developers, dev teams, and organizations, it's easier to work on small "do one thing well" services can change frameworks (or even languages) without a massive cost. As long as the services use a language agnostic protocol (HTTP or lightweight messaging), applications can be written in several different platforms - Java, Ruby, Node, Go, .NET, etc. - without issue. Platform-as-a-Service (PaaS) providers and containers have made it easy to deploy microservices. All the technologies needed to support a monolith (e.g. load balancing, discovery, process monitoring) are provided by the PaaS, outside of your container. Deployment effort comes close to zero. Are Microservices the Future? Architecture decisions, like adopting microservices, are usually only evident several years after you make them. Microservices the Future? Architecture decisions, like adopting microservices the
Future? be successful for your organization. Component to the connections between the components cleanly, you're just shifting complexity from inside a component to the connections between the components cleanly, you're just shifting complexity from inside a component solution. with a microservices architecture. Instead, begin with a monolith, keep it modular, and split it into microservices once the monolith becomes a problem. — Martin Fowler Build a Microservices Architecture with Spring Boot, Spring Cloud, and Netflix Eureka Netflix Eureka is a REST-based service that is primarily used in the AWS cloud for locating services for the purpose of load balancing and failover of middle-tier servers. Spring Cloud is a developer's dream when it comes to implementing and deploying a microservices architecture. discovery, circuit breakers, intelligent routing, micro-proxy, etc.). Coordination of distributed systems leads to boilerplate patterns. Using Spring Cloud, developers can quickly stand up services and applications that implement those patterns. Using Spring Cloud, developers can quickly stand up services and applications that implement those patterns. centers, and managed platforms such as Cloud Foundry. Spring Cloud Netflix provides Netflix OSS integrations for Spring Boot applications. Patterns provided include Service Discovery (Eureka), Circuit Breaker (Hystrix), Intelligent Routing (Zuul) and Client Side Load Balancing (Ribbon). To learn more about service discovery and resolution with Eureka, watch Josh Long's Microservice Registration and Discovery with Spring Cloud and Netflix's Eureka. Create a spring-boot-microservice as an artifact name and select Eureka Server as a dependency. Click the Generate Project button and expand eureka-service.zip into the spring-boot-microservices-example directory. TIP: You could also create your project using start.spring.io's API. The following HTTPie command will create the same app as the steps above: http://www.app.com/app.c dependencies==cloud-eureka-service/src/main/resources/application.properties to add a port number and disable registration.service/src/main/java/com/example/eureka-servic @EnableEurekaServer above @SpringBootApplication. import org.springframework.cloud.netflix.eureka.server; @EnableEurekaServer; @Ena you're using Windows: After it starts, you should be able to open and see there are no services available. Create a Beer Catalog-service for the artifact name and add the following dependencies: Actuator: features to help you monitor and manage your application Eureka Discovery: for service registration JPA: to save/retrieve data H2: an in-memory database Rest Repositories: to expose JPA repositories as REST endpoints Web: Spring MVC and embedded Tomcat DevTools: to auto-reload the application when files change Lombok: to reduce boilerplate code Click the Generate Project button and expand beer-catalogservice.zip into spring-boot-microservices-example and open the project using start.spring.io's API, run the following: http artifactId==beer-catalog-service bootVersion==2.0.5.RELEASE \ name==beer-catalog-service dependencies==actuator, cloud-eureka, data-jpa, h2, data-rest, web, devtools, lombok \ baseDir==beer-catalog-service | tar -xzvf - Create a Beer entity, a JpaRepository for it, and a CommandLineRunner to populate the database with default data. You can add this code to BeerCatalogServiceApplication.java, or create separate files for each class. The code below assumes you're putting all classes in the same file. @Data @AllArgsConstructor @Entity class Beer { public Beer(String name; } @RepositoryRestResource interface BeerRepository extends JpaRepository {} @Component class BeerInitializer implements CommandLineRunner { private final BeerRepository; BeerInitializer(BeerRepository; BeerInitializer("Kentucky Brunch Brand Stout", "Good Morning", "Very Hazy", "King Julius", "Budweiser", "Coors Light", "PBR") .forEach(beer -> beerRepository.save(new Beer(beer))); beerRepository.findAll().forEach(System.out::println); } } If you're using an editor that doesn't auto-import classes, here's the list of imports needed at the top of BeerCatalogServiceApplication.java. import lombok.AllArgsConstructor; import lombok.Data; import org.springframework.boot.CommandLineRunner; import org.springframework.boot.SpringApplication; import org.springframework.boot.autoconfigure.Springframework.boot.autoconfigure.springframework.autoconfigure.springfram org.springframework.data.rest.core.annotation.RepositoryRestResource; import javax.persistence.Entity; import javax.persistence.Entity; import javax.persistence.Id; import javax.persistence.Entity; import javax.persistence.Id; import javax.persiste to display in the Eureka service, and set the port to 8080. server.port=8080 spring.application.name=beer-catalog-service start the beer-catalog-service start st not see the service registered. To register the beer-catalogServiceApplication java. import
org.springBootApplication.java. import org.springBootApplication { public static void main(String[] and (String[] and (S args) { SpringApplication.run(BeerCatalogServiceApplication.class, args); } } Re-compile this class, watch devtools restart your application, and return to . If you're not using an IDE, it might be easiest to cancel and restart mvn spring-boot:run. Now the service should show up. Compile on Save in Intellij IDEA does not automatically compile files when the application is running. To enable the "Compile on save" feature: Go to Preferences > Build, Execution, Deployment -> Compiler and enable "Build project automatically" Open the Action window: Linux: CTRL+SHIFT+A Mac: SHIFT+COMMAND+A Windows: CTRL+ALT+SHIFT+/ Enter Registry... and enable compiler.automake.allow.when.app.running Create an Edge Service will be similar to the standalone beer service created in Bootiful Development with Spring Boot and Angular. However, it will have fallback capabilities which prevent the client from receiving an HTTP error when the service is not available. Navigate to start.spring.io and create an edge-service application with the following dependencies: Eureka Discovery: for service registration Feign: a declarative web service sorvice registration Feign: a declarative web service registration Feign: a declarative web service sorvice registration Feign: a declarative web service registration Feign: a declarative web service sorvice registration Feign: a declarative web service sorvice registration Feign: a declarative web service sorvice registration Feign: a declarative web service registration Feign: a declarative web service registration Feign: a declarative web service sorvice registration Feign: a declarative web service registrative web service registrative web serv cascading failure and enable resilience Lombok: to reduce boilerplate code Click the Generate Project button and expand edge-service.zip into spring-boot-microservice.zip into spring-boot-microservices-example and open the project button and expand edge-service.zip into spring-boot-microservice.zip into spring-boot-microservices-example and open the project button and expand edge-service.zip into spring-boot-microservice.zip into spring-boot-mi bootVersion == 2.0.5.RELEASE \ name == edge-service | tar -xzvf - Since the beer-catalog-service is running on port 8080, you'll need to configure this application to run on a different port. Modify edgeservice/src/main/resources/application.properties to set the port to 8081 and set an application name. server, add the appropriate annotations to EdgeServiceApplication.java: package com.example.edgeservice; import com.netflix.hystrix.contrib.javanica.annotation.HystrixCommand; import lombok.Data; import org.springframework.boot.autoconfigure.Springframework.boot.autoconfigure.springframework.boot.autoc org.springframework.cloud.netflix.feign.EnableFeignClient; import org.springframework.cloud.netflix.feign.EnableFeignClient; import org.springframework.cloud.netflix.feign.FeignClient; import org.springframework.web.bind.annotation.\*; import java.util.ArrayList; import java.util.Collection; import java.util.stream.Collectors; @EnableZuulProxy @SpringBootApplication public class EdgeServiceApplication { public static void main(String[] args) { SpringApplication.run(EdgeServiceApplication.class, args); } } Create a Beer DTO (Data Transfer Object) in this same file. Lombok's @Data class Beer { private String name; } Create a BeerClient interface that uses Feign to talk to the beer-catalog-service public class EdgeServiceApplication { public static void main(String[] args) { SpringApplication.run(EdgeServiceApplication.class, args); } } @Data class Beer { private String name; } @FeignClient("beer-catalog-service") interface BeerClient { @GetMapping("/beers") Resources readBeers(); } Create a RestController below the BeerC out less-than-great beers and exposes a /good-beers endpoint. NOTE: To get beer.getName() to work in your IDE, you may need to install it. Restart Intellij, you can install it. Restart Intellij for the changes to take effect. @RestController class GoodBeerApiAdapterRestController { private final BeerClient; } @GetMapping("/good-beers") public Collectors.toList()); } privatefinal BeerClient; } mixed Beers() { return beerClient; } @GetMapping("/good-beers") public Collectors.toList()); } privatefinal BeerClient; } boolean isGreat(Beer beer) { return !beer.getName().equals("PBR"); } Start the edge-service application with Maven or your IDE and verify it registers successfully with the Eureka server. You should be able to invoke the /good-beers endpoint as well. \$ http://www.able.com/able.co :8081/good-beers HTTP/1.1 200 Content-Type: application/json; charset=UTF-8 Date: Fri, 11 May 2018 17:28:55 GMT Transfer-Encoding: chunked [ { "name": "Kentucky Brunch Brand Stout" }, { "name Brand Stout" }, { "name Brand Stout" }, { "name get a 500 internal server error. \$ http: 8081/good-beers HTTP/1.1 500 Connection: close Content-Type: application/json; charset=UTF-8 Date: Fri, 11 May 2018 17:35:39 GMT Transfer-Encoding: chunked { "error": "Internal Server Error", "message": "connect timed out executing GET , "path": "/good-beers", "status": 500, "timestamp": "2018-05-11T17:35:39.201+0000" } To fix this, you can use Hystrix to create a fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback")
@GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") public Collection fallback() { return new ArrayList(); } @HystrixCommand(fallbackMethod = "fallback") @GetMapping("/good-beers") @GetMapping("/good-beers") @GetMapping("/good-beers") @GetMapping("/good-beers") @GetMapping("/good-beers") @GetMapping("/good-beers") @GetMapping("/good-beers") @GetMapping("/good-beers") an empty list returned. \$ http :8081/good-beers HTTP/1.1 200 Content-Type: application/json; charset=UTF-8 Date: Fri, 11 May 2018 17:38:18 GMT Transfer-Encoding: chunked Start the beer-catalog-service again and this list should eventually return the full list of good beer names. Add an Angular PWA Client You can copy the Angular PWA client I created in a previous tutorial and install its dependencies. git clone cp -r spring-boot-angular-pwa-example/client ~/spring-boot-microservices-example/. cd ~/s this.http.get('); } Modify GoodBeerApiAdapterRestController in EdgeServiceApplication.java to allow cross-origin requests from any client. @GetMapping("/good-beers") @CrossOrigin(origins = "\*") public Collection goodBeers() { Restart the edge-service and start the and verify that network calls to /good-beers go over port 8081. Deploy to Cloud Foundry in order to deploy the edge-service and beer-catalog-service in the edge-service and beer-catalog-service in the edge-service in the edgefollowing: eureka.instance.hostname=\${vcap.application.uris[0]:localhost} eureka.instance.eid:\${spring.application.instance\_id:\${spr eureka.client.registryFetchIntervalSeconds = 5 eureka.client.serviceUrl.defaultZone=\${vcap.services.pwa-eureka eureka.instance.nonSecurePort=80 eureka.instance\_id:\${spring.application.instance\_id:\${spring.appli eureka.client.serviceUrl.defaultZone=\${vcap.services.pwa-eureka-service.credentials.uri}/eureka/ In the properties above, pwa-eureka-service is the name you'll give to the Eureka service when you deploy it to Cloud Foundry. To deploy it on Cloud Foundry with Pivotal Web Services, you'll need to create an account, download/install the Cloud Foundry CLI, and sign-in (using cf login -a api.run.pivotal.io). There are quite a few steps involved to deploy all the services and the Angular client for production. For that reason, I wrote a deploy.sh script that automates everything. TIP: If you receive an error stating that you're using too much memory, you may have to upgrade your Cloud Foundry subscription. When to Use Microservices Building a microservices architecture is something you should consider when you're having difficulty scaling development in a large team. From a development standpoint, moving to microservices will not reduce complexity, but will likely increase it you move to a distributed system. Automation and orchestration are key for deployment. You should make sure to define your exit criteria (e.g. maximum time for a request to execute) before implementing your microservices infrastructure. You're likely going to have to custom build some things, so be prepared for that. Trial a few different platforms and then pick the one that meets your criteria and is the easiest to develop with. Don't develop half of your system on one platform and then try moving to another. Another tip is to make sure and record the request ID in all logging events for traceability. If you have fewer than 20 developers, start with a monolith, but build in async messaging as soon as possible. Use it for things like mail. notifications, logging, and archiving. Debugging, deployment, and logging are much easier with a monolith because everything is contained in one application. Also, consider using async messaging or other non-blocking communication methods with automatic back pressure. HTTP is a synchronous protocol and can be a limiting factor in high-traffic systems. Learn More about Microservice Architectures Spring Boot isn't the only framework to implement embedded servlet containers or make it easy to develop microservices. In Javaland, there's Dropwizard, MicroProfile for Java EE, Lagom, and Vert.x, and Tribestream. You can find the source code for this article's applications on GitHub at
. You can also watch a video of me and Josh Long developing these applications in a YouTube recording of our Cloud Native PWAs presentation at Devoxx France, 2017. If you have any questions about this article, you can email me at matt.raible@okta.com, post a question to Stack Overflow with the Okta tag, post to our Developer Forums, or create an issue on GitHub. Update: To learn about how security fits into all this, see Secure a Spring Microservices Architecture with Spring Security, JWTs, Juiser, and Okta. Update 2: To learn how to lock this application down with Spring Security and OAuth, see Secure a Spring Microservices Architecture with Spring Security and OAuth 2.0. Page 4 JHipster is one of those open-source projects you stumble upon and immediately think, "Of course!" It combines three very successful frameworks in web development: Bootstrap was one of the first dominant web-component frameworks. Its largest appeal was that it only required a bit of HTML and it worked! Bootstrap showed many in the Java community how to develop components for the web. It leveled the playing field in HTML/CSS development, much like Apple's Human Interface Guidelines did for iOS apps. At its core, JHipster is a Yeoman generator. Yeoman is a code generator that you run with a yo command to generate complete applications or useful pieces of an application. Yeoman generators promote what the Yeoman team calls the "Yeoman workflow". This is an opinionated client-side stack of tools that can help developers quickly build beautiful web applications. It takes care of providing everything needed to get working without the normal pains associated with a manual setup. Learn more about JHipster, including its origin, at . This tutorial shows you how to build a microservices architecture with JHipster 4.5.4. You'll generate a gateway, a microservice (that talks to MongoDB), and use Docker Compose to make sure it all runs locally. Then you'll deploy it to Minikube and Google Cloud using Kubernetes. Install JHipster 4 The Installing JHipster instructions show you all the tools you'll need to use a released version of JHipster, you'll need to generate a microservices architecture with JHipster. JHipster Registry You can see how these components fit in the diagram below. To see what's happening inside your applications, you can use the JHipster Console in the Docker Compose section. Create an API Gateway To create a microservices project, open a terminal window and create a jhipster-microservices-example directory. Then create a blog directory for the gateway application. mkdir -p jhipster-microservices-example/blog In JHipster application. This means you can develop it like a monolith, but it also acts as the entrance to your microservices. More specifically, it provides HTTP routing and load balancing, quality of service, security, and API documentation for all microservices. In a terminal, navigate to the blog directory and run jhipster and what features you'd like to include. Create the blog application with the following settings: Application type: Microservice gateway Base name of the application: blog Port: 8080 Default package name: org.jhipster.blog JHipster Registry: Yes Type of authentication: JWT Type of database: SQL Production database: PostgreSQL Development database: H2 with disk-based persistence Maven or Gradle: Maven Other technologies: Elasticsearch Client framework: Angular 4 Sass for CSS: Yes Internationalization support: Yes Native languages: Spanish Testing frameworks: Gatling, Protractor Install other generators from the JHipster Marketplace: No If you'd like to use the same settings I did, you can place the following .yo-rc.json file in the blog directory and run jhipster in it. You won't be prompted to answer any questions because the answers are already in .yo-rc.json. { "generator-jhipster": { "promptValues": { promptValues: { p "org.jhipster.blog", "packageFolder": "org/jhipster/blog", "serverPort": "8080", "authenticationType": "jwt", "hibernateCache": "hazelcast", "clusteredHttpSession": false, "websocket": false, "databaseType": "h2Disk", "prodDatabaseType": "postgresql", "searchEngine": "elasticsearch", "messageBroker": false, "databaseType": "h2Disk", "prodDatabaseType": "h2Disk", "prodDatabaseType": "postgresql", "searchEngine": "elasticsearch", "messageBroker": false, "databaseType": "h2Disk", "prodDatabaseType": "h2Disk", "prodDatabaseType": "postgresql", "searchEngine": "elasticsearch", "messageBroker": false, "databaseType": "h2Disk", "prodDatabaseType": "h2Disk", "h2Disk", "prodDatabaseType": "h2Disk", "prodDatabaseType": "h2Disk", "prodDatabaseType": "h2Disk", "h2Disk "serviceDiscoveryType": "eureka", "buildTool": "maven", "enableSocialSignIn": false, "jwtSecretKey": "f7450a034a7251b3d201cf5139852f9adf69c2d1", "clientFrameworks": [ "gatling", "protractor" ], "jhiPrefix": "jhi", "enableTranslation" true, "nativeLanguage": "en", "languages": [ "en", "es" ] } The project creation process will take a couple of minutes to run, depending on your internet connection speed. When it's finished, you should see output like this: Before you can run this project, you'll need to download and start an instance of the JHipster Registry. Run the following commands in the jhipster-microservices-example directory. git clone git@github.com:jhipster/jhipster-registry.git registry cd registry is built on Spring Cloud Netflix and Spring Cloud Netflix include Service Discovery (Eureka), Circuit Breaker (Hystrix), Intelligenter-microservices-example directory. git clone git@github.com:jhipster/jhipster-registry.git registry && yarn && ./mvnw The JHipster Registry is built on Spring Cloud Netflix and Spring Cloud Netflix include Service Discovery (Eureka), Circuit Breaker (Hystrix), Intelligenter-microservices-example directory.git clone git@github.com:jhipster-registry.git registry && yarn && ./mvnw The JHipster Registry is built on Spring Cloud Netflix and Spring Cloud Netflix include Service Discovery (Eureka), Circuit Breaker (Hystrix), Intelligenter-microservices-example directory.git clone git@github.com:jhipster-registry.git registry && yarn && ./mvnw The JHipster Registry is built on Spring Cloud Netflix and Spring Cloud Netflix include Service Discovery (Eureka), Circuit Breaker (Hystrix), Intelligenter-microservices-example directory.git clone git@github.com:jhipster-registry.git registry && yarn && ./mvnw The JHipster Registry is built on Spring Cloud Netflix and Spring Cloud Netflix and Spring Cloud Netflix include Service Discovery (Eureka), Circuit Breaker (Hystrix), Intelligenter-microservices-example directory.git clone git@github.com:jhipster-registry.git registry && yarn && ./mvnw The JHipster Registry && yarn && ./mvnw The JHipster Registry && yarn && ./mvnw The JHipster Registry & Routing (Zuul), and Client Side Load Balancing (Ribbon). In a previous post, I showed you how you can use Eureka for service discovery. JHipster Registry is a Eureka server, a Spring Cloud Config server, as well as an administration server. It includes dashboards to monitor and manage your JHipster Registry starts on port 8761 by default. In a new terminal window, navigate to jhipster-microservices-example/blog and run ./mvnw to start the blog application and open in your favorite browser. The first thing you'll notice is a dapper-looking fellow explaining how you can sign in or register. Sign in with username admin and password admin and you'll have access to navigate through the Administration section. This section offers nice looking UIs on top of some Spring Boot's many monitoring and configuration features. It gives you insights into Application and JVM metrics: And it allows you to see the Swagger docs associated with its API. You can run the following command (in a separate terminal window) to start the Protractor tests and confirm everything is working properly. At this point, it's a good idea to check your project into Git so you can easily see what changes are made going forward. git init git add . git commit -m "Gateway created" Shut down your blog application before proceeding to the next section. Generate Entities For each entity you want to create, you will need: A database table A Liquibase change set A JPA entity class A Spring Data JpaRepository interface A Spring Data JpaRepository interface A Spring Data JpaRepository interface A Spring MVC RestController class An Angular model, state, component, dialog components, service Several HTML pages for each component Also, you should have integration tests to verify that everything works and performance tests to verify that it runs fast. In an ideal world, you'd also have unit tests and integration tests for you, including integration tests and performance tests. In addition, if you have entities with relationships, it will generate the necessary schema to support them (with foreign keys), and the TypeScript and HTML code to manage them. You can also set up validation to require certain fields, as well as control their length. JHipster supports several methods of code generator. The entity sub-generator. The entity sub-generator is a command-line tool that prompts you with questions which you answer. JDL-Studio is a browser-based tool for defining your domain model with JHipster Domain Language (JDL). Finally, JHipster-UML is an option for those that like UML. Supported UML editors include Modelio, UML Designer, GenMyModel, and Visual Paradigm. I like the visual nature of JDL-Studio, so I'll use it for this project. Below is the entity diagram and JDL code needed to generate a simple blog with blogs, entries, and tags. You can click on this URL, or copy/paste the contents of the file below to your hard drive if you'd like to follow along. entity Blog { name String required minlength(3), handle String required minlength(2) } entity Entry { title String required, content TextBlob required, date ZonedDateTime required ate ZonedDateTime directory) to import this
file. Running this command will generate entities, tests, and a UI. jhipster import-jdl ~/Downloads/jhipster-jdl.jh You'll be prompted to overwrite this file, as well as others. Start the application with /.mvnw and run yarn start (in another window) to view the UI for the generated entities. Create a couple of blogs for the existing admin and user users, as well as a few blog entries. From these screenshots, you can see that users can see each other's data, and modify it. Now, check your generated entities into Git. git init git add . git commit -m "Entities generated" Add Business Logic TIP: To configure an IDE with your JHipster project, see Configuring your IDE. Instructions exist for Eclipse, IntelliJ IDEA, Visual Studio Code, and NetBeans. To add more security around blogs and entries, open BlogResource.java and find the getAllBlogs() method. Change the following line: List blogs = blogRepository.findAll(); To: List blogs = blogRepository.findByUserIsCurrentUser(); The findByUserIsCurrentUser() method is generated by JHipster in the BlogRepository class and allows limiting results by the current user. public interface BlogRepository extends JpaRepository { @Query("select blog from Blog blog where blog.user.login = ?#{principal.username}") List findByUserIsCurrentUser(); } After making this change, re-compiling BlogResource should trigger a restart of the application thanks to Spring Boot's Developer tools. If you navigate to you should only see the blog for the current user. To add this same logic for entries, open EntryResource.java and find the getAllEntries() method. Change the following line: Page page = entryRepository.findAll(pageable); To: Page page = entryRepository.findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using your IDE, create this method in the EntryRepository class. It should look as follows: Page findByBlogUserLoginOrderByDateDesc(String currentUserLogin(), pageable); Using yo Pageable pageable); Recompile both changed classes and verify that the user user only sees the entries you created for them. After making this changes, commit them to Git. git add . git commit -m "Add business logic" You might notice that this application doesn't look like a blog and it doesn't allow HTML in the content field. Make UI Enhancements When doing UI development on a JHipster-generated application, it's nice to see your changes as soon as you save a file. JHipster 4 uses Browsersync and webpack to power this feature. You enable this previously by running the following command in the blog directory. In this section, you'll change the rendered content field to display HTML Change the list of entries to look like a blog Allow HTML If you enter HTML is no longer escaped on the list screen. To change this behavior, open entry.component.html and change the following line: {{entry.content}} To: After making this change, you'll see that the HTML is no longer escaped Improve the layout To make the list of entries look like a blog, replace with HTML, so it uses a stacked layout in a single column. {{entry.title}} by {{entry.blog.user.login}} Edit Delete Now it looks more like a regular blog! Commit all your changes to Git. git add . git commit -m "UI enhancements" Create a Microservice To generate a store microservice, open a terminal window and navigate to the jhipster-microservices-example mkdir store cd store jhipster use the following settings to generate a microservice that uses MongoDB for its database. Application type: Microservice application Base name of the application: store Port: 8081 Default package name: org.jhipster.store Type of database: MongoDB Maven or Gradle: Maven Other technologies: None Internationalization support: Yes Native language: English Additional languages: Spanish Testing frameworks: Gatling Install other generators from the JHipster Marketplace: No The .yo-rc.json created by this process is as follows: { "generator-jhipster": "4.5.4", "baseName": "org.jhipster.store", "packageName": "org.jhipster.store", "packageFolder": { "promptValues": { promptValues: { "org/jhipster/store", "serverPort": "8081", "authenticationType": "jwt", "hibernateCache": "no", "clusteredHttpSession": false, "websocket": false, "kebsocket": false, "kebs "enableSocialSignIn": false, "jwtSecretKey": "ea21b5b635606be4d7937e29926166e0ee56abb1", "enableTranslation": true, "skipUserManagement": true, "skipUserManagement": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "skipUserManagement": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhiPrefix": "jhi", "skipClient": true, "applicationType": "microservice", "testFrameworks": [ "gatling" ], "jhiPrefix": "jhi your changes to Git. It's always a good idea to do this before generating entities. cd ~/jhipster-microservices-example/ git add store git commit -m "Generate store application" Generate Product Entity by running the following command in the store directory. Use the following answers for the questions asked: Do you want to add a field to your entity? Yes What is the name of your field? name What is the type of your field? String Do you want to add a field to your entity? Yes What is the name of your field? Price What is the type of your field? BigDecimal Do you want to add a field to your entity? Yes What is the name of your field? The type of your field? BigDecimal Do you want to add a field to your entity? Yes What is the type of your field? BigDecimal Do you want to add a field to your entity? to add validation rules to your field? Yes Which validation rules do you want to add? Required Do you want to add a field to your entity? No Do you want to use a Data Transfer Object (DTO)? No Do you want to use separate service class for your business logic? No Do you want to use a Data Transfer Object (DTO)? look similar to the following after you've answered all these questions. Generate UI for Product Entity A microservice only contains the server-side code for the entities it contains. To generate an Angular UI for the product, navigate to the blog directory and run the same command. Use the following answers to the questions asked: Do you want to generate this entity from an existing microservice? Yes Enter the path to the microservice root directory: ../store Do you want to update the entity? Yes A visual of these questions and answers is in the screenshot below. Commit your changes to Git. cd ~/jhipster-microservices-example git add . git commit -m "Add product entity" At this point, you should be able to verify everything works by starting the registry, blog, store, and MongoDB. You can run MongoDB using Docker Compose section shows how you can run all your services using Docker. Navigate to , log in with admin/admin, and go to Entities > Product. You should be able to add a product and see that it has a MongoDB identifier. Build for Product. You should be able to add a product and
see that it has a MongoDB identifier. its JAR files. JHipster ships with support for deploying to Cloud Foundry, Heroku, Kubernetes, AWS, and AWS with Boxfuse. When you prepare a JHipster application for production, it's recommended to use the pre-configured "production" profile. With Maven, you can package your application by specifying the prod profile when building. The production profile is used to build an optimized JavaScript client. You can invoke this using webpack by running yarn run webpack:prod. The production profile also configures gzip compression with a servlet filter, cache headers, and monitoring via Metrics. If you have a Graphite server configured in your application-prod.yml file, your application will automatically send metrics data to it. When you run this command in the blog application, you'll likely get a test failure. Results : Failed tests: BlogResourceIntTest.getAllBlogs:184 Status expected: but was: Tests run: 157, Failures: 1, Errors: 0, Skipped: 0 The reason this happens is shown in a stack trace in your terminal. Running org.jhipster.blog.web.rest.BlogResourceIntTest 2017-06-19 10:29:17.288 ERROR 4168 --- [ main] o.j.b.w.rest.errors.Exception is java.lang.IllegalArgumentException: Authentication object cannot be null 2017-06-19 10:29:17.472 ERROR 4168 --- [ main] o.j.blog.web.rest.util.HeaderUtil : Entity processing failed, A new blog cannot already have an ID To fix this, you can use Spring Security Test's @WithMockUser. Open BlogResourceIntTest.java and inject UserRepository as a dependency. @Autowired private UserRepository userRepository; Change the createEntity() method, so it's not static and uses the userRepository to set a user on the blog entity. public Blog createEntity(EntityManager em) { Blog blog = new Blog() .name(DEFAULT NAME) .landle(DEFAULT NAME) .landle(DEFAU getAllBlogs() throws Exception { Commit your changes to Git. git add . git commit -m "Fix tests" After fixing this test, you should be able to run ./mvnw -Pprod package without any failures. You might notice that this does take quite some time, mostly due to the Webpack build and optimizations. Below is the output from a Mid 2015 MacBook Pro with 16GB of RAM and JAVA OPTS set to -Xmx2048m. [INFO] [INFO] BUILD SUCCESS [INFO] [INFO] Total time: 04:38 min [INFO] Finished at: 2017-06-19T10:39:09-06:00 [INFO] Final Memory: 75M/747M [INFO] ----- Deploy to the Cloud What good is a microservices architecture if it's not deployed to a PaaS (Platform as a Service)?! PaaS providers are also known as "the cloud", and allow you to deploy and scale microservices as needed. Docker provides are also known as "the cloud", and allow you to deploy and scale microservices as needed. operating system and services needed to run your application. Often, Docker containers are used for the individual components of your architecture. For example, you'll have a Docker container for each app, as well as one for PostgreSQL, MongoDB, and Elasticsearch. To complete this section, you'll need to install Docker. NOTE: If you're not on Mac or Windows, you may need to install Docker Compose as well. Run with Docker Compose is a tool for defining and running multi-container Docker applications. With Compose is a tool for defining and running multi-container being and running multi-container being and start all the components of your application with a single command. Make sure Docker is running Build Docker images for the blog and store applications by running the following command in both directories: ./mvnw package -Pprod docker:build Using your terminal, navigate to the root directory of your project, and create a docker directory of your microservices: ./ Applications to include: blog and store Applications with clustered databases: None Set up monitoring: [Hipster Console with ELK/Zipkin The admin password for the JHipster Registry: admin Run docker-compose up to run all your services and see the logs in the same window. Add -d if you want to run them as a daemon Use Kitematic to view the ports and logs for the services deployed You can view the JHipster Registry at . To produce data for the JHipster Console to display, run some Gatling tests in the blog app. These simulations can take a while (> 10m) to complete. When they're finished, you can view their pretty reports. You can see the JHipster Console at . Navigate to Dashboards > Open to display some pre-built dashboards for the JVM, logs, metrics, microservices, and performance. The screenshots below show you what some of these look like. To save your changes for Docker Compose, commit your changes to Git. git add . git commit -m "Add Docker Compose" Run with Kubernetes and Minikube Kubernetes is an open-source system for automating deployment, scaling, and management of containerized applications. It was developed at Google over the last 16 years and was internally called Borg. To deploy bocker containers with Kubernetes, you set up a cluster, then deploy to it. The context can be local (with Minikube), or remote (e.g. a Raspberry Pi cluster, Google Cloud, AWS, OpenShift, etc.). Follow the steps below to use Kubernetes to deploy to a local cluster. Install kubectl, VirtualBox and Minikube start To be able to work with the docker daemon, run the following command in your terminal: eval \$(minikube docker-env) Create Docker images of the blog and store applications: ./mvnw package -Pprod docker:build Using your terminal, navigate to the root directory of your project, and create a kubernetes sub-generator in it. Application Root directory of your microservices: ../ Applications to include: blog and store The admin password for the JHipster Registry: admin Kubernetes namespace: default Base Docker repository name (e.g. mraible): Command to push Bocker images. The Kubernetes sub-generator says to run docker push as well, but you don't need that for a Minikube deployment. docker image tag blog mraible/blog docker image tag store mraible/store Run the following commands in the kubernetes directory to deploy -f store The deployment process can take several minutes to complete. Run minikube dashboard to see the deployed containers. You can also run kubectl get po -o wide --watch to see the status of each pod. Run minikube service blog to view the blog application. You should be able to login and add blogs, entries, and products. To remove all deployed containers, run the following command: kubectl delete deployment --all To stop Minikube, run minikube stop. To save your changes for Kubernetes, commit your changes to Git from the top-level directory. git add . git commit -m "Kubernetes" Deploy to Google Cloud is a PaaS that's built on Google Cloud. If you completed the Minikube section above, open a new terminal window to reset things. Create a Google Cloud google.com Navigate to to initialize the Container Engine for your project at console.cloud.google.com Navigate to to initialize the Container Section above, open a new terminal window to reset things. Create a Google Cloud SDK and set project using: gcloud config set proj scopes cloud-platform --zone us-west1-a To see a list of possible zones, run gcloud compute zones list. Push the blog and store docker images to Docker Hub. You will need to create an account and run docker push mraible/blog docker image tag store mraible/store docker push mraible/store Run kubectl apply -f registry app locally kubectl apply -f store Use port-forward in get the external IP of the blog application on Google Cloud Open http://:8080 to view your running application and verify everything works. Scale microservice apps as needed with kubectl: kubectl scale --replicas=3 deployment/store Did you get everything working? If so, you rock! You've built a production-ready microservice scaffold for your application with JHipster! Issues Found While creating this example, I ran into a few issues. Alert translations not resolved in the gateway for microservice entities. The workaround is to open the src/main/webapp/i18n/\*/product.json files and move the keys from storeApp to blogApp. See issue #5960 for more information. In production mode, new entries don't show in the list. The logs have an error like the following: 2017-06-19 18:08:06.930 ERROR 17597 --- [XNIO-2 task-62] o.j.b.w.rest.errors.ExceptionTranslator : An unexpected error occured: Unable to access lob stream This is a known issue with PostgreSQL. Adding @Transactional to the EntryResource.java class definition solved this problem. When running everything in Minikube, adding new products fails. Upgrading to JHipster Registry 3.0.2 solved this issue. See this commit to see how to upgrade. Source Code and Screencast The source code for this tutorial is available on GitHub. See its README if you simply want to clone the project and run it. Or, you can watch a screencast of building microservices with JHipster and deploying to Google Cloud. Learn More about JHipster and Microservices I hope you've enjoyed learning how JHipster can help you develop hip microservices architectures! It's a nifty project, with an easy-to-use entity generator, a beautiful UI, and many Spring Boot best-practice patterns. If you have features you'd like to add or if you'd like to refine existing features, you can watch the project on GitHub and help with its development and support. We're always looking for help! If you have questions about JHipster, please hit me up on Twitter or post a question to Stack Overflow with the "jhipster" tag. If you're interested in learning more about microservices, you might also find the following resources useful: Page 5 There's a lot of confusion around what OAuth as a "security thing", and don't really know much more than that. I'm going to show you what OAuth is, explain how it works, and hopefully leave you with a sense of how and where OAuth can benefit your application. What Is OAuth? To begin at a high level, OAuth is not an API or a service: it's an open standard that apps can use to
provide client applications with "secure delegated access". OAuth works over HTTPS and authorizes devices, APIs, servers, and applications with access tokens rather than credentials. There are two versions of OAuth 2.0. These specifications are completely different from one another, and cannot be used together: there is no backwards compatibility between them. Which one is more popular? Great question! Nowadays, OAuth 2.0 - as it's most likely what you'll be using. Why OAuth? OAuth? OAuth? OAuth? OAuth? OAuth? I'm talking about OAuth 2.0 - as it's most likely what you'll be using. pattern was made famous by HTTP Basic Authentication, where the user is prompted for a username and password. Basic Authentication is still used as a primitive form of API authentication; instead of sending a username and password to the server with each request, the user sends an API key ID and secret. Before OAuth, sites would prompt you to enter your username and password directly into a form and they would login to your Gmail account) as you. This is often called the password anti-pattern. To create a better system for the web, federated identity was created for single sign-on (SSO). In this scenario, an end user talks to their identity provider, and the identity provider generates a cryptographically signed token which it hands off to the application trusts the identity provider. As long as that trust relationship works with the signed assertion, you're good to go. The diagram below shows how this works. Federated identity was made famous by SAML 2.0, an OASIS Standard released on March 15, 2005. It's a large spec but the main two components are its authentication request protocol (aka Web SSO) and the way it packages identity attributes and signs them, called SAML assertions. Okta does this with its SSO chiclets. We send a message, we sign the assertion, inside the assertion it says who the user is, and that it came from Okta. Slap a digital signature on it and you're good to go. SAML SAML is basically a session cookie in your browser that gives you access to webapps. It's limited in the kinds of device profiles and scenarios you might want to do outside of a web browser. When SAML 2.0 was launched in 2005, it made sense. However, a lot has changed since then. Now we have modern web and native application development platforms. There are Single Page Applications (SPAs) like Gmail/Google Inbox, Facebook, and Twitter. They have different behaviors than your traditional web application, because they make AJAX (background HTTP calls) to APIs. Mobile phones make API calls too, as do TVs, gaming consoles, and IoT devices. SAML SSO isn't particularly good at any of this. OAuth and APIs A lot has changed with the way we build APIs too. In 2005, people were invested in WS-\* for building web services. Now, most developers have moved to REST and stateless APIs. REST is, in a nutshell, HTTP commands pushing JSON packets over the network. Developers build a lot of APIs. The API Economy is a common buzzword you might hear in boardrooms today. Companies need to protect their REST APIs in a way that allows many devices to access them. In the old days, you'd enter your username/password directory and the app would login directly as you. This gave rise to the delegated authorization problem. "How can I allow an app to access my data without necessarily giving it my password?" If you've ever seen one of the dialogs below, that's what we're talking about. This is an application framework for REST/APIs. It enables apps to obtain limited access (scopes) to a user's data without giving away a user's password. It decouples authentication from authorization and supports multiple use cases addressing different device capabilities. It supports multiple use cases addressing different device capabilities. It supports multiple use cases addressing different device capabilities. like hotel key cards, but for apps. If you have a hotel key card, you can get access to your room. How do you get a hotel key card? You have to do an authentication process at the front desk to get it. After authentication process at the front desk to get it. authorization from User User authorizes App and delivers proof of authorization to server to get a Token S Authorization Server S Authorizat Flows OAuth Scopes are what you see on the authorization screens when an app requests permissions. They're bundles of permissions asked for by the client when requesting a token. This is the first key aspect of OAuth. The permissions are front and center. They're not hidden behind the app layer that you have to capture this consent. This is called trusting on first use. It's a pretty significant user experience change on the web. Most people before OAuth were just used to name and password dialog boxes. Now you have to train users to use. Retraining the internet population is difficult. There are all kinds of users from the tech-savvy young folk to grandparents that aren't familiar with this flow. It's a new concept on the web that's now front and center. Now you have to authorize and bring consent. The consent can vary based on the application. It can be a time-sensitive range (day, weeks, months), but not all platforms allow you to choose the duration. One thing to watch for when you consent is that the app can do stuff on your behalf - e.g. LinkedIn spamming everyone in your network. OAuth is an internet-scale solution because it's per application. You often have the ability to log in to a dashboard to see what applications you've given access to and to revoke consent. OAuth Actors The actors in OAuth flows are as follows: Resource Owner of my Facebook profile. Resource Server: The API which stores data the application wants to access your data Authorization Server: The main engine of OAuth The resource owner is a role that can change with different credentials. It can be an end user, but it can also be a company. Clients can be public and confidential. There is a significant distinction between the two in OAuth nomenclature. Confidential clients can be trusted to store a secret. They're not running in a protected area where end users can't access them. Public clients are browsers, mobile apps, and IoT devices. Client registration is also a key component of OAuth. It's like the DMV of OAuth. You need to get a license plate for your application. This is how your app's logo shows up in an authorization dialog. OAuth Tokens Access tokens are the token the client uses to access the Resource Server (API). They're meant to be short-lived. Think of them in hours and minutes, not days and month. You don't need a confidential client to get an access token. You can get access tokens with public clients. They're designed to optimize for internet scale problems. Because these tokens can be short lived and scale out, they can't be revoked, you just have to wait for them to time out. The other token is the refresh token. This is much longer-lived; days, months, years. This can be used to get new tokens. To get a refresh token. To get a refresh token. This is much longer-lived; days, months, years. This can be used to get new tokens. To get a refresh token. This gives you the ability to force the clients to rotate secrets. What you're doing is you're spec doesn't define what a token is. It can be in whatever format you want. Usually though, you want these tokens to be JSON Web Tokens (a standard). In a nutshell, a JWT (pronounced "jot") is a secure and trustworthy standard for token authentication. JWTs allow you to digitally sign information (referred to as claims) with a signature and can be verified at a later time with a secret signing key. To learn more about JWTs, see A Beginner's Guide to JWTs in Java. Tokens are retrieved from endpoints on the authorize endpoint and the token endpoints are the authorize endpoint and the token endpoint are the authorize endpoint. consent and authorization from the user. This returns an authorization grant that says the user has consented to it. Then the authorization is passed to the token endpoint. The token endpoint. The token endpoint. The token endpoint. The token endpoint and says "great, here's your refresh token and your access token". You can use the access token to get access to APIs. Once it expires, you'll have to go back to the token endpoint with the refresh token to get a new access token. The downside is this causes a lot of developer friction. One of the biggest pain points of OAuth for developers is you having to manage the refresh tokens. You push state management onto each client developer. You get the benefits of key rotation, but you've just created a lot of pain for developers. That's why developers love API keys. They can just copy/paste them, slap them in a text file, and be done with them. API keys are very convenient for the developers, but very bad for security, but there's more friction. There are opportunities for toolkits and platforms to simplify things and help with token management. Luckily, OAuth is pretty mature these days, and chances are your favorite language or framework has tools available to simplify things. We've talked a bit about the client types, the token types, and the endpoints of the authorization server and how we can

pass that to a resource server. I mentioned two different flows: getting the authorization and getting the tokens. Those don't have to happen on the same channel is what goes over the browser. The browser redirected the user to the authorization server, the user gave consent. This happens on the user's browser. Once the user takes that authorization grant and hands that to the application, the client application no longer needs to use the browser to complete the OAuth flow to get the tokens. The tokens are meant to be consumed by the client application so it can access resources on your behalf. We call that the back channel is an HTTP call directly from the client application to the resource server to exchange the authorization grant for tokens. These channels are used for different flows depending on what device capabilities you have. For example, a Front Channel Flow where you authorize via user agent might look as follows: Resource Owner starts flow to delegate access to protected resource Client sends authorization request with desired scopes via browser redirect to the Authorization Server Authorization Server Authorization so if you're not authenticated to your Resource Server, it'll ask you to login. If you already have a cached session cookie, you'll just see the consent dialog box. View the consent dialog box. View the consent dialog, and agree. The authorization grant is passed back to the application via browser redirect. minute. This is what it looks like on the wire. Request GET gmail.send & redirect uri = & response type=code&client id=812741506391 & state=af0ifjsldkj This is a GET request with a bunch of query params (not URL-encoded for example purposes). Scopes are from Gmail's API. The redirect uri = & response type=code&client id=812741506391 & state=af0ifjsldkj This is a GET request with a bunch of query params (not URL-encoded for example purposes). authorization grant should be returned to. This should match the value from the client registration process (at the DMV). You don't want the authorization being bounced back to a foreign application. Response type varies the OAuth flows. Client ID is also from the registration process. State is a security flag, similar to XRSF. To learn more about XRSF, see DZone's "Cross-Site Request Forgery explained". Response HTTP/1.1 302 Found Location: code=MsCeLvIaQm6bTrgtp7&state=af0ifjsldkj The code returned is the authorization grant and state is to ensure it's not forged and it's from the same request. After the Front Channel is done, a Back Channel Flow happens, exchanging the authorization code for an access token. The Client application sends an access token request to the token endpoint on the Authorization Code Grant for an Access Token and (optionally) a Refresh Token. Client accesses a protected resource with Access Token. Below is how this looks in raw HTTP. Request POST /oauth2/v3/token HTTP/1.1 Host: www.googleapis.com Content-Type: application/x-www-form-urlencoded code=MsCeLvIaQm6bTrgtp7&client id=812741506391&client secret={client secret}&redirect url= grant type is the extensibility part of OAuth. It's an authorization code from a precomputed perspective. It opens up the flexibility to have different ways to describe these grants. This is the most common type of OAuth flow. Response { "access token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "3600, "refresh token": "360 You can be reactive or proactive in using tokens. Proactive is to have a timer in your client. Reactive is to catch an error and attempt to get a new token then. Once you have an access token, you can use the access token in an Authentication header (using the token\_type as a prefix) to make protected resource requests. curl -H "Authorization: Bearer 2YotnFZFEjr1zCsicMWpAA" \ So now you have a front channel, a back channel, different endpoints, and different clients. You have to mix and match these for different clients. You have to mix and match these for different clients. because all the communication is happening through the browser. There is no backend server redeeming the authorization grant for an access token. An SPA is a good example of this flow is also called 2 Legged OAuth. Implicit flow is optimized for browser-only public clients. An access token is returned directly from the authorization request (front channel only). It typically does not support refresh tokens. It assumes the Resource Owner and Public Client are on the same device. Since everything happens on the browser, it's the most vulnerable to security threats. The gold standard is the Authorization Code Flow, aka 3 Legged, that uses both the front channel and the back channel. This is what we've been talking about the most in this article. The front channel flow is used by the client application to exchange the authorization code grant. The back channel is used by the client application to obtain an authorization code grant. and Client Application are on separate devices. It's the most secure flow because you can authenticate the client to redeem the authorization Code flows, there are additional flows you can do with OAuth. Again, OAuth is more of a framework. For server-to-server scenarios, you might want to use a Client Credential Flow. In this scenario, the client application is a confidential client that's acting on its own, not on behalf of the user. It's more of a service account type of scenario. All you need is the client's credentials to do the whole flow. It's a back channel only flow to obtain an access token using the client's credentials. It supports shared secrets or assertions as client credentials signed with either symmetric keys. Symmetric keys. Symmetric bey cryptographic algorithms are cryptography, or asymmetric cryptography, is any cryptographic system that uses pairs of keys: public keys and private keys are sacred to the owner. This allows data to be secure without the need to share a password. There's also a legacy mode called Resource Owner Password Flow. This is very similar to the direct authentication with username and password scenario and is not recommended. It's a legacy grant type for native username/password apps such as desktop applications. In this flow, you send the client application a username/password apps such as desktop applications. assumes the Resource Owner and Public Client are on the same device. For when you have an API that only wants to speak OAuth, but you have and evice. For when you have an API that only wants to speak OAuth, but you have an API that only wants to speak OAuth. Authorization Server to trust authorization grants from the token endpoint. This is great for companies that have invested in SAML or SAML-related technologies and allow them to integrate with OAuth. Because SAML assertions are short-lived, there are no refresh tokens in this flow and you have to keep retrieving access tokens every time the assertion expires. Not in the OAuth spec, is a Device Flow. There's no web browser, just a controller for something like a TV. A user code is returned from an authorization request that must be redeemed by visiting a URL on a device with a browser to authorize. A back channel flow is used by the client application to poll for authorization approval for an access token and optionally a refresh token. Also popular for CLI clients. We've covered six different flows using the different flows using the different flows using the different flows. how we needed to get consent from the client, who is making consent, and that adds a lot of complexity to OAuth. When people ask if you support all six flows, or just the main ones? There's a lot of granularity available between all the different flows. Security and the Enterprise There's a large surface area with OAuth. With Implicit Flow, there's lots of redirects and lots flow integrity Always whitelist redirect URIs to ensure proper URI validations Bind the same client to authorization grants and token requests with a client secret in your app that's distributed through an App Store! The biggest complaint about OAuth in general comes from Security people. It's regarding the Bearer tokens and that they can be passed just like session cookies. You can pass it around and you're good to go, it's not cryptographically bound to the user. Using JWTs helps because they can't be tampered with. used in an Authorization header. Enterprise OAuth 2.0 Use Cases OAuth decouples your authorization. It can replace traditional Web Access Management (WAM) Policies. It's also great for restricting and revoking permissions when building apps that can access specific APIs. It ensures only managed and/or compliant devices can access specific APIs. It has deep integration with identity deprovisioning workflows to revoke all tokens from a user or
device. Finally, it supports federation with identity deprovisioning workflows to revoke all tokens from a user or device. of OAuth 2.0: it's not backwards compatible with OAuth 1.0. It replaces signatures with HTTPS for all communication. When people talk about OAuth today, they're talking about OAuth 1.0. It replaces signatures with HTTPS for all communication. When people talk about OAuth 1.0. It replaces signatures with HTTPS for all communication. When people talk about OAuth 1.0. It replaces signatures with HTTPS for all communication. When people talk about OAuth 1.0. It replaces signatures with HTTPS for all communication. When people talk about OAuth 2.0. Because OAuth is an authorization framework and not a protocol, you may have interoperability issues. and you might need custom code to integrate with vendors. OAuth 2.0 is not an authentication protocol. It even says so in its documentation. We've been talking about the user. You just have a token to get access to a resource. There's a huge number of additions that've happened to OAuth in the last several years. These add complexity back on top of OAuth to complete a variety of enterprise scenarios. For example, JWTs can be used as interoperable tokens that can be signed and encrypted. Pseudo-Authentication with OAuth 2.0 Login with OAuth was made famous by Facebook Connect and Twitter. In this flow, a client accesses a /me endpoint with an access token. All it says is that the client has access token. All it says is that the client has access token. All it says is that the client has access token. All it says is that the client has access token. All it says is that the client has access token. All it says is that the client has access token. nothing in the standards that say everyone has to implement this endpoint. Access tokens are meant to be opaque. They're not designed to contain user information. What you're really trying to answer with authenticate. You can typically answer these questions with SAML assertions, not with access tokens and authorization grants. That's why we call this pseudo authentication problem, the best parts of OAuth 2.0, Facebook Connect, and SAML 2.0 were combined to create OpenID Connect. OpenID Connect (OIDC) extends OAuth 2.0 with a new signed id\_token for the client and a UserInfo endpoint to fetch user attributes. Unlike SAML, OIDC provides a standard set of scopes and claims for identities. Examples include: profile, email, address, and phone. OIDC was created to be internet scalable by making things completely dynamic. There's no longer downloading metadata and federation like SAML requires. There's built-in registration, discovery, and metadata for dynamically downloads the metadata, dynamically know what certs it's going to use, and allows BYOI (Bring Your Own Identity). It supports high assurance levels and key SAML use cases for enterprises. OIDC was made famous by Google and Microsoft, both big early adopters. Okta has made a big investment in OIDC as well. All that changes in the initial request is it contains standard scopes (like openid and email): Request GET scope=openid email& redirect\_uri= response\_type=code& client id=812741506391& state=af0ifjsldkj Response HTTP/1.1 302 Found Location: code=MsCeLvIaQm6bTrgtp7& state=af0ifjsldkj The code returned is the authorization grant and state is to ensure it's not forged and it's from the same request. And the authorization grant for tokens response contains an ID token. Request POST /oauth2/v3/token HTTP/1.1 Host: www.googleapis.com Content-Type: application/x-www-form-urlencoded code=MsCeLvIaQm6bTrgtp7&client id=812741506391& client secret}& redirect uri= grant type=authorization code Response { "access token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "Bearer", "expires in": 3600, "refresh token": "2YotnFZFEjr1zCsicMWpAA", "token type": "3600, "refresh token": "3600, "refresh token"; "3600, "refresh token; "360 "tGzv3JOkF0XG5Qx2TlKWIA", "id\_token": "eyJhbGciOiJSUz11NiIsImtpZCI6IjFlOWdkazcifQ..." } You can see this is layered nicely on top of OAuth to give back an ID token is a JSON Web Token (JWT). A JWT (aka "jot") is much smaller than a giant XML-based SAML assertion and can be efficiently passed around between different devices. A JWT has three parts: a header, a body, and its signed in the signature. The header says what algorithm was used to sign it, the claims are in the body, and its signed in the signature. keys and optionally dynamically register the Client application Validate JWT ID token locally based on built-in dates and signature Get additional user attributes as needed with access token OAuth + Okta is best known for its single-sign on services that allow you to seamlessly authenticate to the applications you use on a daily basis. But did you know Okta also has an awesome developer platform? Secure single sign-on often uses SAML as the protocol of choice, but Okta also provides several other options, including a Sign-in Widget, Auth SDK (a JavaScript-based library), Social Login, and an Authentication API for any client. If you're interested in learning about Okta straight from the source, you should attend Oktane17 in late August. There's a track dedicated to app development. See Okta's OIDC/OAuth 2.0 API for specific information on how we support OAuth. SAML is implemented by Okta with its SSO chiclets. If you're an Okta customer, like me, you likely interact with most apps using something like . When you click on a chiclet, we send a message, we sign the assertion, inside the assertion it says who the user is, and that it came from Okta. Slap on a digital signature on it and you're good to go. If you'd rather watch a video to learn about OAuth, please see the presentation below from Nate Barbettini, Product Manager at Okta. OAuth 2.0 is an authorization framework for delegated access to APIs. It involves clients that request scopes that Resource Owners authorize/give consent to. Authorization grants are exchanged for access to kens and refresh tokens between Authorization Servers and Resource Servers. OAuth has a very large security surface area. Make sure to use a secure toolkit and validate all inputs! OAuth is not an authentication protocol. OpenID Connect extends OAuth 2.0 for authentication scenarios and is often called "SAML with curly-braces". If you're looking to dive even deeper into OAuth 2.0, I recommend you check out OAuth.com, take Okta's Auth SDK for a spin, and try out the OAuth flows for yourself. If you're passionate about OAuth 2.0 and OIDC, we suggest the following posts: If you're passionate about OAuth and OIDC, we suggest the following posts: If you're passionate about OAuth and OIDC like we are, give us a follow on Twitter or check out our new security site where we're publishing indepth articles on security topics. Page 6 Every good dev knows that time spent setting up the perfect environment and searching out the latest tools is time well spent. Little things make a huge difference — upgrade your IDE plugins, automate a task or two, or look for new tools and libraries that can increase your efficiency. We've taken a crack at an updated list of our favorite .NET developer tools, that can simplify your life and amplify your work. 1. JSON.NET Chances are that for any given project these days, you'll be consuming a RESTful JSON API, producing one, or both. And even if you're not, you may still be using JSON to serialize data or configuration on disk. Sure, you could get it done using System.Runtime.Serialization.Json, but JSON.NET is faster and has tons of nice features to make your life easier. Built-in LINQ-to-JSON using XPath-like syntax has earned this library the reputation as the de facto JSON implementation for .NET. 2. .NET API Browser (and Reverse Package Search) Here's a two-for-one for our second tool suggestion: the .NET API Browser and Reverse Package Search. As classes get moved around when their packages are invaluable for tracking everything down. Microsoft's .NET API Browser is a comprehensive reference for all classes and methods in the .NET API. The best part is that it autocompletes while you type, making it easy to locate APIs even when you can't remember exactly where they exist in the package hierarchy. Similarly, the Reverse Package Search lets you quickly search a vast collection of third party libraries, tagged with their respective supported versions of .NET Framework or .NET Core. It's a little less curated than Microsoft's official API browser, but the breadth makes up for it. 3. StyleCop. Analyzers If there's one thing
that can really get a team of developers fussed up, it's adhering to a consistent code formatting style. The only real solution is to adopt a formatting tool like StyleCop, and then share the configuration throughout the team. StyleCop can detect and fix a broad range of style offences, and can even be set up in some IDEs to work real-time as you type. StyleCop.Analyzers is the latest incarnation of this project. Okta's very own .NET evangelist Nate is a dedicated contributor. 4. Visual Studio Code visual Studio Code is Microsoft's open source text editor and IDE. It's beautiful and featureful and a joy to use. Not just for .NET, it works well with lots of language ecosystems and runs on Mac, Linux, and Windows. It's got some similarities to Atom, but comes with IntelliSense, debugger, git integration, and can be extended even further with plugins. 5. Posh-git Been working for days on a major feature branch when a critical issue pops up in production? No worries: just commit to your feature branch, switch to the stable branch to push a fix, and switch back. Git (and its equivalent for Subversion, Mercurial, and Perforce) modifies your shell prompt to include the current branch and other status information. It also provides tab-completion for your SCM commands and branch names, which results in a very nice git experience. 6. ReSharper ReSharper restaus information. It also provides tab-completion for your SCM commands and branch names, which results in a very nice git experience. assistance. From on-the-fly "quick fixes" to project-wide symbol renaming, this tool is like having your own co-pilot. It costs a few hundred bucks per year, but it should quickly pay for itself in increased productivity, and it comes with a 30-day trial so you can take it for a test drive. Combine it with the StyleCop plugin and get the benefits of code format evaluation as you type. 7. xUnit.net If you've invested in good unit test coverage, then you're undoubtedly pretty committed to a testing framework already. But if you're starting a new project, or just haven't got around to writing any tests yet (we won't judge) then look no further than xUnit.net. It is the successor to NUnit, and builds on the long lineage of similarly-named testing frameworks in other languages such as JUnit, CPPUnit, and dozens more easier to maintain, and a focus on data-driven testing using theories. xUnit has made some opinionated deviations to promote clearer more isolated tests that are easier to maintain, and a focus on data-driven testing using theories. by providing the scaffolding to put them on. It supplies the infrastructure for basic fixturing and test running (including in parallel), and combines nicely with AutoFixture and Moq for writing concise and effective unit tests. Bonus - FluentAssertions On the topic of writing concise and effective unit tests. expressive assertions. When a test fails, it's important to be able to know why without reaching for the debugger. The possibilities for tweaking and refining your development workflow go on and on. While shiny new tools have the potential to dramatically increase productivity, it's easy to go down the rabbit hole of research and not actually get any work done. So now that you've got some new tricks, you can stop reading and go put them to work. Page 7 In the age of the "personalized web experience", authentication providers like Facebook, Twitter, and Google. And it's not just the wild, wild web that needs it. Businesses need ways to secure their APIs, and identify users logged into their apps. OpenID Foundation describing the best way for the authenticating users. It is a specification by the OpenID Foundation describing the best way for the authenticating users. It is a specification by the OpenID Foundation describing the best way for the authenticating users. It is a specification by the OpenID Foundation describing the best way for the authenticating users. It is a specification by the OpenID Foundation describing the best way for the authenticating users. "OpenID Connect Certified" which makes it easier than ever to consume authentication as a service. Why Not Use OAuth 2.0? First, OAuth 2.0 OAuth 2.0 does a great job of providing the necessary information for consumers to make authorization decisions, it says nothing about how that information will be exchanged securely. This has led to a few well-publicized hacks. OpenID Connect fixes these problems by providing an authentication protocol that describes exactly how the exchange of authorization information happens between a subscriber and their provider. So let's see how this works. Nothing Up My Sleeve You'll be using Visual Studio Code and the command line. You can also use Visual Studio, but Visual Studio Code is cross-platform and lightweight, so it won't matter what operating system you are using. First, get the dotnet command. This will create a new MVC application without the built-in authentication. You're going to do that yourself. In just a few seconds you'll have a simple ASP.NET Core app ready to go. You may need to run a dotnet restore command to install the dependencies for the base application. Add an Identity Provider Now you need an Identity Provider. For this tutorial you'll use Okta. Once you've created an account and logged in, click Admin on the top menu. Then choose the Applications menu item from the admin dashboard. From the Add Application button. We'll choose Web from the Platform dropdown, and OpenID Connect from the Add Application button. We'll choose Web from the Platform dropdown, and OpenID Connect from the Add Application button. Sign On Method. Once you've created the applications. In the General Settings tab, scroll down and copy your Client ID and Client Secret somewhere. You'll use this later when configuring the middleware in your application. Finally, you'll need to make sure that you can use the API by adding the localhost URI to your CORS settings. First, choose the Security menu item from the dashboard and the choose API from the drop down menu. Then select the Trusted Origins tab. Click on Add Origin and add as a trusted origin. Make sure that CORS and Redirect are selected. Enter "ASP.NET web app (debug)" as the redirect name (or any other name that makes sense to you). Now you're ready to set up authentication! Add Authentication When you open your application in Visual Studio or Visual Studio get some dependencies you'll need to make this work. In the ItemGroup section of the csproj document add: This will allow you to use ISON Web Tokens for authorization information, get the tokens from the OpenID Connect provider (Okta in this case) and store them in cookies for session management. You'll need to run a guick dotnet restore command, but don't worry, once you save the file, VS Code will give you an option to return to the command line. Now, open the Startup.cs file, and on the first line of the Configure method add: using Microsoft.IdentityModel.Tokens; Then, between the app.UseStaticFiles(); and app.UseMvc(...); add: app.UseCookieAuthentication(new CookieAuthenticationOptions() { AuthenticationScheme = "Cookies", AutomaticAuthentication instructions. app.UseOpenIdConnectAuthentication(new OpenIdConnectOptions() { AuthenticationScheme = "oidc", SignInScheme = "cookies", Authority = "https://{yourOktaDomain}", ResponseType.Code, ClientId = "{clientId}", ClientSecret = "{clientId}", ClientSecret}", GetClaimsFromUserInfoEndpoint = true, The Authority identifies the authorization endpoint for your Identity Provider. It's discoverable as part of the OpenID specification, and is located at: https://{yourOktaDomain}/oauth2/default/.well-known/openid-configuration. The Response\_type is also specified in that document under "response\_types\_supported". start an authorization code flow from from the provider. The ClientId, and ClientSecret are the Client ID and Client Secret you got from the General Settings tab. For production, I would highly suggest storing these in a secure way and referencing them here. They're in line here for demonstration purposes. Setting GetClaimsFromUserInfoEndpoint = true tells the provider that if you're successful authenticating, go ahead and make a call to the userinfo\_endpoint (specified in the configuration document at the same URL you got the authentication has completed. This will get the claims that we're going to display from Okta once the authentication has completed. The TokenValidationParameters tells the middleware that we want to validate that the issuer is who we expect it to be by getting the signing key from the jwks\_uri endpoint in the .well-known/openid\_configuration document. Finally, we tell the application to save the token once it comes back from the provider. That's all there is to it, but how do you know it's working? Well, you could hook up a login form but there is an easier way! Check Your Work All you really need to do is add an [Authorize] attribute to a controller method. That will simply and quickly show us that it's going to the login page on the provider, but it won't show us what the provider is sending back. Let's create a page that will show that information so you can make sure you're getting what you should be getting from the provider. First, add a using statement to the HomeController. [Authorize] public IActionResult Secure() + return View(); } Then create a view to return in ~/Views/Home called Security.cshtml. @{ ViewData["Title"] = "Security"; } Secure @foreach (var claim in User.Claims) { @claim.Type @claim.Value } This will just loop through the claims and output them. When you navigate to you should be redirected to a login page. Once you're logged in (with a user that is assigned to your app), you should now see a list of the claims on the secure page. If you do, congratulations! You just set up OpenID Connect for authenticating in your ASP.NET Core app! If you have any questions, feel free to reach out to me via
email, or hit me up in the comments or via Twitter @leebrandt. Page 8 My favorite thing about Apache Shiro is how easy it makes handling authorization. You can use a role-based access control (RBAC) model of assigning roles to users and then permissions to roles. In this post I want to demonstrate just how simple it is, using a Spring Boot application and walking through how I'd handle the following scenario: Your boss (The Supreme Commander) shows up at your desk and tells you the current volunteer (Stormtrooper) registration application needs have different access roles for the different types of employees Officers can register new "volunteers" Underlings (you and I) only have read access the volunteers" It should go without saying the Supreme Commander has access to everything Start with a REST Application To get started, grab this Spring Boot example. It'll get you started with a set of REST endpoints which expose CRUD operations to manage a list of Stormtroopers. You'll be adding authentication and authorization using Apache Shiro. All of the code is up on GitHub. Using the Apache S org.apache.shiro shiro-spring-boot-web-starter \${shiro.version} Jumping into the code we will start with our StormtrooperController, and simply add annotations: @RestController { private final StormtrooperDao trooperDao; @Autowired public StormtrooperController(StormtrooperDao = trooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"admin", "officer", "underling"}) public Collection listTrooperDao; } @GetMapping Logical.OR, value = {"admin", "officer", "underling"}) public Stormtrooper getTrooper(@PathVariable("id") String id) throws NotFoundException(id); } return stormtrooper = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } return stormtrooper; } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } @PostMapping() @RequiresRoles(logical = null) { throw new NotFoundException(id); } @PostMapping() @RequiresRoles(logical = null) { throw Logical.OR, value = {"admin", "officer"}) public Stormtrooper createTrooper(@RequestBody Stormtrooper updatedTrooper); } @PostMapping(path = "/{id}") @RequiresRoles("admin") public Stormtrooper updateTrooper(@PathVariable("id") String id, @RequestBody Stormtrooper updatedTrooper) throws NotFoundException { return trooperDao.updateStormtrooper(id, updatedTrooper); } @DeleteMapping(path = "/{id}") @ResponseStatus(value = HttpStatus.NO\_CONTENT) @Respons @RequiresRoles annotation to describe your use-case. You'll notice the logical OR to allow any of these roles access. This is great, your code is done, it was pretty easy to add, just a single line. You could stop here but, roles are not that flexible, and if you put them directly in your code you're now tightly coupled to those names/IDs. Stop Using Roles Imagine your application has been deployed and is working fine, the following week your boss stops by your desk and tells you to to make a few small changes to the method signatures: @GetMapping() @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "emperor", "admin", admin", admin", admin, admin getTrooper(@PathVariable("id") String id) throws NotFoundException @PostMapping() @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper createTrooper(@RequestBody Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}")
@RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) public Stormtrooper trooper) @PostMapping(path = "/{id}") @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin", "officer"}) "officer"}) public Stormtrooper updateTrooper(@PathVariable("id") String id, @RequestBody Stormtrooper updatedTrooper) throws NotFoundException @DeleteMapping(path = "/{id}") @ResponseStatus(value = HttpStatus.NO\_CONTENT) @RequiresRoles(logical = Logical.OR, value = {"emperor", "admin"}) public void deleteTrooper(@PathVariable("id") String id) After another round of testing the deployment and you're back in action! Wait, take a step back. Roles are great for simple use cases and making a change like this would work fine, but you know this will be changed again. Instead of changing your code every time the requirements change slightly, let's decouple the roles and what they represent from your code. Instead, use permissions. Your method signatures will look like this: @GetMapping() @RequiresPermissions("troopers:read") public Collection listTroopers() @GetMapping() and a second and a second a throws NotFoundException @PostMapping() @RequiresPermissions("troopers:create") public Stormtrooper createTrooper(@PostMapping(path = "/{id}") @RequiresPermissions("troopers:create") public Stormtrooper updateTrooper(@PostMapping(path = "/{id}") @RequiresPermissions("troopers:create") public Stormtrooper updateTrooper(@RequestBody Stormtrooper update throws NotFoundException @DeleteMapping(path = "/{id}") @ResponseStatus(value = HttpStatus.NO\_CONTENT) @RequiresPermissions("troopers:delete") public void deleteTrooper(@PathVariable("id") String id) By using Shiro's @RequiresPermissions annotation, this code would work with the original requirements and the new requirements without modification. The only thing that changes is how you map those permissions to roles, and in turn, to users. This could be done externally from your application in a database, or for this example a simple properties file. NOTE: This example a simple properties and passwords all stored as clear text, this is fine for a blog post, but seriously, manage your passwords correctly! To meet the original requirements, the role-to-permission mapping would look like this: role.admin = troopers:read For the updated requirements, you would just change the file slightly to add the new 'emperor' role, and grant officers the 'update' permission: role.emperor = \* role.admin = troopers:read, troopers:read, troopers:read, troopers:read, troopers:read If the permission documentation for an in depth explanation. Apache Shiro and Spring We've already covered the Maven dependencies and the actual REST controller, but our application will also need a Realm and error handling. If you take a look at the SpringBootApp class you will notice a few things that were NOT in the original example. @Bean public Realm realm() { // uses 'classpath:shiro-users.properties' by default PropertiesRealm realm = new PropertiesRealm(); // Caching isn't needed in this example, but we can still turn it on realm.setCachingEnabled(true); return realm; } @Bean public ShiroFilterChainDefinition(); // use permissive to NOT require authentication, our set of the controller Annotations will decide that chainDefinition.addPathDefinition.addPathDefinition; } @Bean public CacheManager () { // Caching isn't needed in this example, but we will use the MemoryConstrainedCacheManager(); } First you have defined a Shiro Realm, a realm is simply a user-store specific DAO. Shiro supports many different types of Realms out of the box (Active Directory, LDAP, Database, file, etc.). Next up you have the ShiroFilterChainDefinition which you've configured to allow BASIC authentication but NOT required it by using the 'permissive' option. This way your annotations configure everything. Instead of using annotations (or in addition to using them) you could define your permission to URL mappings with Ant-style paths. This example would look something like: chainDefinition.addPathDefinition.ad /troopers to require BASIC authentication, and use the 'rest' filter which based on the HTTP request method, appends a CRUD action to the permission string for a 'GET' request would be troopers:read (just like you did with your annotations). Exception Handling The last bit of code you have handles exceptions. @ExceptionHandler(UnauthenticatedException.class) @ResponseStatus(HttpStatus.FORBIDDEN) public void handleException(UnauthenticatedException(UnauthenticatedException.class)) @ResponseStatus(HttpStatus.FORBIDDEN) public void handleException(UnauthenticatedException.class)) @ResponseStatus(HttpStatus.FORBIDDEN) public void handleException(UnauthenticatedException(UnauthenticatedException.class)) @ResponseStatus(HttpStatus.FORBIDDEN) public void handleException(UnauthenticatedException.class)) @ResponseStatus(HttpStatus.FORBIDDEN) public void handleException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(UnauthenticatedException(Unauthen void handleException(AuthorizationException e) { log.debug("{} was thrown", e.getClass(), e); } @ExceptionHandler(NotFoundException.class) @ResponseBody ErrorMessage(); return new ErrorMess +", why aren't you at your post? "+ id +", do you copy?"); } The first two handle Shiro exceptions and simply set the status to 401 or 403. A 401 for any valid logged in user that does NOT have access to the resource. Lastly, you'll want to handle any NotFoundException with a 404 and return a JSON serialized ErrorMessage object. Fire it Up! If you put all of this together, or you just grab the code from GitHub, you can start the application using mvn spring-boot:run. Once you have everything running you can start the application using mvn spring-boot:run. realm="application" Don't forget, you need to authenticate! \$ curl --user emperor:secret HTTP/1.1 200 Content-Type: application/json; charset=UTF-8 Date: Thu, 26 Jan 2017 21:14:17 GMT Transfer-Encoding: chunked [ { "id": "FN-0128", "planetOfOrigin": "Naboo", "species": "Twi'lek", "type": "Sand" }, { "id": "FN-1383", "planetOfOrigin": "Hoth" "species": "Human", "type": "Basic" }, { "id": "FN-1692", "planetOfOrigin": "Hoth", "species": "Nikto", "type": "Marine" }, ... A 404 looks would look like this: \$ curl --user emperor:secret HTTP/1.1 404 Content-Type: application/json;charset=UTF-8 Date: Thu, 26 Jan 2017 21:15:54 GMT Transfer-Encoding: chunked { "error": "Trooper Not Found: TK 421, why aren't you at your post? TK-421, do you copy?" } Learn More About Apache Shiro This example has shown how easy it is to integrate Apache Shiro into a Spring Boot application, how using permissions allow for greater flexibility over roles, and all it takes is a single Annotation in your controller. At Stormpath we were happy to be able to commit our support to Apache Shiro, and we've carried that commitment forward to Okta. Look forward to more Shiro content from our team, including tutorials on using Shiro with Okta and OAuth plus how to add an AngularJS frontend to this example you can send them to Apache Shiro's user list, me on Twitter, or just leave them in the comments section below! To learn more, check out these posts: Page 9 Progressive Web Apps, aka PWAs, are the best way for developers to make their webapps load faster and more performant. In a nutshell, PWAs are websites that use recent web standards to allow for installation on a user's computer or device, and deliver an app-like experience with PWAs, showing that the technology is finally ready for the masses. In this guide, you'll learn about the essential ingredients in a PWA, how to install one, why you should build one, and how they stack up
against hybrid and native applications. A Deeper Dive - What is a PWA? A PWA is a web application that can be "installed" on your system. It works offline when you don't have an internet connection, leveraging data cached during your last interactions with the app. If you're on a desktop, using Chrome, and have the appropriate flags turned on, you will be prompted to install the app when you visit the site. For example, enable the following URLs into Chrome. //flags/#enable-add-to-shelf chrome://flags/#bypass-app-banner-engagement-checks Click the blue "Relaunch Now" button at the bottom of your browser after enabling these flags. Now if you visit a site like, you'll see an installation prompt at the top of the page. Click the "Add" button and you'll see a dialog to name the app, populated with information from the app is manifest. This adds the applications/Chrome Apps" directory. on a Mac. If you launch the apps, they will run in Chrome rather than having their own icon. On an Android phone, their icon and launch behavior will resemble that of a native application. You can use Chrome's Developer Tools > Network tab to toggle "Offline" and reload the application. You can use Chrome's Developer Tools > Network tab to toggle "Offline" and reload the application. You can use Chrome's Developer Tools > Network tab to toggle "Offline" and reload the application. You can use Chrome's Developer Tools > Network tab to toggle "Offline" and reload the application. reach the server. Why Should You Build a PWA? You should make your webapp into a PWA because it'll reduce the time it takes for your app to load and it'll give your users a better experience. Having it load over HTTPS is a good security practice and adding icons (using a web app manifest) is something you'd do anyway. Having a cache-first service worker strategy will allow your app to work offline (if the user has already loaded data), alleviating one of the biggest issues with webapps. There are a number of other performance recommendations you can implement the PRPL pattern: Push critical resources for the initial URL route. Render initial route. Pre-cache remaining routes on demand. Use to tell your browser to load a resource you know you'll eventually need. This is a W3C Standard specification. Use HTTP/2 and server push to "push" assets to the browser without the user having to ask for them. Use code-splitting and lazy-loading for granular loading of application pages/features. Mariko Kosaka created some drawings to show the difference between HTTP/2 nicely. Note that HTTP/2 nicely. Note that HTTP/2 nicely. Note that HTTP/2 nicely. you're going to build a PWA and leverage service workers, you should become familiar with Chrome Developer Tools' Application tab. This tab provides the ability to manipulate service workers, you should because everything will be cached in your browser and when you update files in your editor, they won't be reloaded in your browser. For a great resource on Chrome's Developer Tools, I recommend Umaar Hunsa's Dev Tips. Developers have been fighting for ages to get the browser to not cache assets, so PWAs kinda go against the grain for web developers. One workaround is to comment out your service worker in your index.html. For example: If your app is so dynamic that you don't want anything cached, a PWA might not be right for you. However, you should still look into serving it over HTTP/2 for better security and faster performance. PWAs and Hybrid Apps vs. Mobile Apps app is large and you can't load parts of it lazily (meaning loading it on-demand rather than at the beginning), bundling it all up in a hybrid app with Cordova might make sense. If your app does intense tasks or is highly interactive (like a game), coding it with native SDKs is likely a good option. If you're interested in learning more about using Cordova with Ionic and Spring Boot, you can check out my recent tutorial. PWAs are useful for apps like Twitter and news sites because they have a lot of text that you'll read, but not necessarily interact with. Having it as a PWA allows you to open the app, load its data, then read its contents later when you're offline. This should work in a normal web application, but I've noticed that some browsers will try to reload the page when you open them, resulting in a dreaded "server not found" error. However, neither of these techniques will help your users with slow connections and less powerful smartphones. Even if you choose to create a lightweight PWA app that can load in seconds and give your users something to work with. PWAs are the way of the future, and the now. Most browsers support it, with notably absent support on iOS when they only supported web apps on the first iPhone. However, they do list service workers as "under consideration" in WebKit. Meanwhile, Google is championing the effort, with vast amounts of documentation on PWAs, dedicated developer advocates for PWAs, and many conference sessions on the subject at Google I/O 2017. Sam Delgado believes "If it weren't for Apple, hybrid app development would be the clear winner over native". In this article he laments that there's one major disadvantage to the hybrid approach for iOS: you still have to go through Apple's complicated setup for Xcode, provisioning profiles, needing a Mac to compile, using TestFlight for betas, and the app review process. The iOS webView is another reason the experience isn't great. WKWebView offers a better experience, but requires some hacky workarounds. He ends the article noting that the "Hybrid vs Native" debate will likely continue until Apple has many reasons to say no to PWAs, but they won't allow Android to offer a better web experience. Jason Grigsby writes, "Despite the fact that iOS doesn't support the full feature set of Progressive Web Apps, early evidence indicates that Progressive Web Apps, early evidence indicates that Progressive Web Apps, early evidence indicates that Progressive Web Apps perform better on iOS than the sites they replace." Not only that, but PWAs offer a lower cost mobile presence. Yes, there are some additional cons like some native APIs not being available and that you can't find PWAs in the App Store or Google Play. The native API issues might be around for awhile, but the ability to locate an app by URL (versus searching a store) seems easier to me. Chrome and Android have deep integration for PWAs. According to the Chromium Blog: When installed, PWAs appear in the app drawer section of the launcher and in Android Settings, and can receive incoming intents from other apps. Long presses on their notification management controls for Chrome. Developers have pondered if PWAs should be findable in Google Play. So far, Google has not released any plans to do so. Another thing to consider is how much WebStorage on the device your application will need. Eiji Kitamura conducted research on quotas for mobile browsers in 2014 and found that most browsers support up to 10MB of LocalStorage. More storage is typically available in Application Cache, IndexedDB, and WebSQL, but only on desktop browsers. For example, Firefox on Android allows the Application Cache to use up to 500MB on desktop, but only 5MB on mobile. Users can change this quota on their device, but the application developer cannot control this setting. You can see the quotas for your browser by visiting Browser Storage Abuser. So, what do you need to know to start building? PWA Requirements: HTTPS, Service Workers, and Web App Manifest The requirements for a PWA can be quickly added to almost any web application. All you need to do is the following: Deploy it to a public web server and force HTTPS. Create and include a JavaScript file with code to cache network requests. Create and include a web app manifest. To see how to add these features to an Angular application, see my Build Your First Progressive Web Application with Angular and Spring Boot blog post on Okta's developer blog. This article shows you how to add a service worker, a manifest with icons, and deploy it to CloudFoundry with HTTPS. Not only that, but it scores a 98/100 using the Lighthouse Chrome Extension. Scott Domes has a similar tutorial that will walk you through the basics of building a PWA in React. Angular will soon have built-in service worker support. Create React App (a popular starter tool for React) now has PWAs by default as one of its features. PWA Reference Apps and Stats HN PWA is a reference for how to build efficient PWAs with different frameworks. It's similar to TodoMVC, but for progressive web apps. For each framework, it includes its Lighthouse score and time to interactive over a slow connection, as well as a faster 3G connection. performance gained by implementing progressive Web App install banners. The Forbes Progressive Web App install banners convert 5-6x more often than native install banners. The Forbes Progressive Web App install banners convert 5-6x more often than native install banners. Progressive Web Apps in 62 languages to 178 countries. CSS Tricks notes that two other PWA galleries exist: pwa-directory.appspot.com pwa.rocks Framework Support for PWA features already exist in some of the more popular JavaScript framework application generators. However, you don't need to have these features created for you, you can also add them to an existing application. HTTPS has gotten much easier with free certificates from Let's Encrypt and AWS Certificates from Let's Encrypt and Heroku. Heroku also has support for automated certificate management using Let's Encrypt. You can generate a manifest.json file and icons for your PWA using and . For online/offline data syncing, you can use solutions like IndexedDB, PouchDB, or roll your own with the Background Sync API. This feature is available in Chrome desktop and Android since version 49. Angular You can add services a manifest.json file and icons for your PWA using and . For online/offline data
syncing, you can use solutions like IndexedDB, PouchDB, or roll your own with the Background Sync API. worker support and app shell for offline Angular 2+ applications. With native service worker support headed to Angular Soon, you can tell the Angular Soon and the Soon and Angular CLI. You will need to run a command: ng set apps.0.service-worker = true, but @angular/service-worker is not installed, you will see a message: Your project is configured with service-worker = true, but @angular/service-worker is not installed. Run `npm install --save-dev @angular/service-worker is not installed, you will see a message: Your project is configured with service-worker = true, but @angular/service-worker is not installed. Run `npm install --save-dev @angular/service-worker = true, but @angular/service-worker is not installed. Run `npm install --save-dev @angular/service-worker is not installed. Run `npm install --save-dev @angular/service-worker = true, but @angular/service-worker is not installed. Run `npm install --save-dev @angular/service-worker is not installed. Run `npm install --save-dev @angular/service-worker = true, but @angular/service-worker is not installed. Run `npm install --save-dev @angular/service-worker is not insta apps.0.serviceWorker=false` in your .angular-cli.json. Ionic is a framework that leverages Angular to create native apps with web technologies. It leverages Angular to deploy your app to the web. See my tutorial about developing mobile applications with Ionic and Spring Boot to learn more. Below is a screenshot of the completed application in the tutorial. NativeScript is another option for developing mobile apps with Angular. The big difference between it and Ionic is that it uses the native platform's rendering engine instead of WebViews. NativeScript does not support building PWAs. React When (version 1.0+), a manifest is generated, and an offline-first caching strategy service worker. If you already have a React application, Create React App's 1.0 release notes tell you how to turn your app into a PWA. Preact is an alternative im vou create a React apt Dication using Create React Ai lementation of React that's built for speed. It's a much smaller library (~3KB) that implements the same ES6 API, components, and Virtual DOM support as React. Using it instead of React means your application will have less JavaScript to download, parse, and execute. Vue.js has a command line tool called Vue-CLI. Addy Osmani recently added a PWA template, so you can generate a new Vue.js PWA app with the following commands: npm install -g vue-cli vue init pwa my-pwa-project If you already have a Vue.js application, see Charles Bochet's article on creating a PWA with Vue.js. Learn More I love apps that work when I'm offline, especially when flying and traveling. Internet connectivity can be spotty when you're moving and apps that don't require connectivity are great. For instance, I wrote the first draft of this article on my phone using Google Docs, without service. Although Google Docs, without service. Although Google Docs isn't a PWA, it demonstrates the allure of making your web apps have similar features, we should embrace them and use them! It's a great time to be a web developer; we can make the web better together. If you're interested in staying up to date on what's happening in the PWA world, I recommend following Alex Russell (@slightlylate), Addy Osmani (@addyosmani), and Sean Larkin (@thelarkinn) on Twitter. Or, you can check out any of these great resources: Example Applications Ready to get your feet wet building an app? You can find some interesting PWA tutorials here: Page 10 In the beginning, there were proprietary approaches to working with external identity providers for authentication and authorization. Then came SAML (Security Assertion Markup Language) - an open standard using XML as its message exchange type. Then, there was OAuth and OAuth 2.0 - also open as well as being a modern, RESTful approach to authorization using JSON as its medium. And now, the holy grail of "secure delegated access" OpenID Connect (henceforth OIDC), which runs on top of OAuth 2.0. But wait. What was wrong with OAuth 2.0? To understand better, let's first dispense with the term, secure delegated access. It's too vague and has led to confusion between authentication, you'd have to trust that every application, and every developer not only had your best interests and privacy in mind, but also knew how to protect your identity and was willing to keep up with security best practices. That's a pretty tall order, right? With OIDC, you can use a trusted external provider to prove to a given application that you are who you say you are, without ever having to grant that application access to your credentials. OAuth 2.0 leaves a lot of details up to implementers. For instance, it supports scopes, but scope names are not specified. It supports access tokens, but the format of those tokens and ID tokens. An ID token must be JSON web token (JWT). Since the specification dictates the token format, it makes it easier to work with tokens across implementations. In this blog series, I share a primer on OIDC. In the first post, we'll review some key concepts around OIDC and tokens, explained in human terms. Then, we'll look at OIDC in action with some specific code examples to highlight its value in the authentication and authorization ecosystem. Finally, we'll dig into the guts of the different token types and how to control what goes into them. You can see the various concepts and OIDC interactions covered at: The code that backs this is at: Key Concepts: Scopes, Claims, and Response Types Before we dive into the minutiae of OIDC, let's take a step back and talk about how we interact with it. There are two primary actors involved in all OIDC interactions: the OpenID Provider (OP) and the Relying Party (RP). The OP is an OAuth 2.0 server that is capable of authenticating the end-user and providing information about the result of the authentication and the end-user to the Relying Party. The Relying Party is an OAuth 2.0 application that "relies" on the OP to handle authentication endpoint with an HTTP GET. A number of query parameters indicate what you can expect to get back after authenticating and what you'll have access to (authorization). Often, you'll need to hit a /token endpoint with an HTTP POST to get tokens which are used for further interactions. OIDC also has an /introspect endpoint for getting identity information about the user. All of the above endpoints are the convention, but can be defined by the OP to be anything. One of the great improvements in OIDC is a metadata mechanism to discover endpoints from the provider. For instance, if you navigate to: you'll get back a JSON formatted document with the metadata that identifies all the available endpoints from the OP (Okta, in this case). What's a Scope? Scopes are space-separated lists of identifiers used to specify what access privileges are being requested. Valid scope identifiers are specified in RFC 6749. OIDC has a number of built in scope are: scope purpose profile requests access to default profile claims email requests access to email and email verified claims address requests access to address to phone number and phone number and phone number verified claims are: name family name given name middle name nickname preferred username profile picture website gender birthdate zoneinfo locale updated at Notice how the scopes are tied to claims. You may be asking, what the heck are claims? What's a Claim? Simply put, claims are name/value pairs that contain information about the OIDC service. The official definition from the spec is a "piece of information about a user, as well meta-information about the OIDC service. That's because the request for the user's info was made using a token that was obtained with the profile scope. In other words, a request is made that
results in the issuance of a token. That token contains certain information based on the scopes specified in the original request. What's a Response Type? When working with OIDC, you'll hear talk of various "flows". These flows are used to describe different common authentication and authorization scenarios. Considerations include the type of application (like web-based or native mobile app), how you want to access additional identity information (make another API call or have it encoded right into a token). There are three primary flows: Authorization Code, Implicit, and Hybrid. These flows are controlled by the response type query parameter in the /authorization request. When thinking of which flow to use, consider front-channel vs. back-channel refers to a user-agent (such as a SPA or mobile app) interacting directly with the OpenID provider (OP). The implicit flow is a good choice when front-channel communication is required. Back-channel refers to a middle-tier client (such as Spring Boot or Express) interacting with the OP. The authorization code flow is a good choice when back-channel communication is required. authentication, the response will contain a code value. This code can later be exchanged for an access token and an id token (Hang in for now, we'll talk about tokens in more depth later on.) This flow is useful where you have "middleware" as part of the architecture. The middleware "as part of the architecture. The middleware" as part of the architecture. code for tokens by hitting the /token endpoint. These tokens can then be returned to the end-user application, such as a browser, without the browser ever having to know the client secret. This flow allows for long-lived sessions through the use of refresh tokens. The only purpose of refresh tokens is to obtain new access tokens to extend a user session. Implicit flow uses response type=id token or response type=id token in the first case or just an id token in the second case. This flow is useful when you have an app speaking directly to a backend to obtain tokens with no middleware. It does not support long-lived sessions. Hybrid flow combines the above two in different combinations - whatever make sense for the use case. An example would be response type=code id token. This approach enables a scenario whereby you can have a long lived session in an app and get tokens back immediately from the /authorization endpoint. All About Tokens With the foundation of scopes, claims, and response types, we can now talk about tokens! There are three types of tokens in OIDC: id token and refresh token and the token and the token can be definitively verified to prove that it hasn't been tampered with. There's a set of rules in the specification for validating an id token. Among the claims encoded in the id token is an expiration (exp), which must be honored as part of the validation process. Additionally, the signature section of JWT is used in concert with a key to validate that the entire IWT has not been tampered with in any way. A Brief History of IWTs In the beginning tokens were opague - they carried no intrinsic information. This was fine as the server knew the token and could look up any data related to it, such as identity information. When the OAuth 2.0 spec was released in 2012, it defined token types (such as access and refresh tokens), but it purposely avoided dictating the format of these tokens. In 2015, the JWT spec was released. It proposed the creation of tokens which encoded other information. This token could be used as an opaque identifier and could also be inspected for additional information. The spec also includes provisions for cryptographically signed JWTs (called JWSs) and encrypted JWTs (called JWEs). A signed JWT is particularly useful in application development because you can have a high degree of confidence that the information encoded into the JWT has not been tampered with. By verifying the JWT within the application, you can avoid another round trip to an API service. It also allows to enforce behavior, like expiration, because you know the exp claim has not been altered. There's no direct relationship between JWT and OAuth 2.0. However, many OAuth 2.0. formalizes the role of JWT in mandating that ID Tokens be JWTs. Many OIDC implementers will also use JWTs for access and refresh tokens, but it is not dictated by the spec. Access tokens are used as bearer tokens, but it is not dictated by the spec. important that bearer tokens are protected. If I can somehow get ahold of and "bear" your access token limiting the exposure of the fact that it's a bearer token. Although not mandated by the OIDC spec, Okta uses IWTs for access tokens as (among other things) the expiration is built right into the token. OIDC specifies a /userinfo endpoint that returns identity information and must be protected. Presenting the access token makes the endpoint accessible. Here's an example using HTTPie: http HTTP/1.1 400 Bad Request ... WWW-Authenticate: Bearer error="invalid request", error description="The access token is missing." ... Let's try again with an expired access to 401 Unauthorized ... WWW-Authenticate: Bearer error="invalid\_token", error\_description="The token has expired." ... Finally, let's try with a valid access token: http \ Authorization: "Bearer eyJhbGciOiJSUz11NiIsImtpZCI6Ik93bFNJS3p3Mmt1Wk8zSmpnMW5Dc2RNelJhOEV1elY5emgyREl6X3RVRUkifQ..." HTTP/1.1 200 OK ... { "family\_name": "Silverman", "given name": "Micah", "groups": [ "ABC123", "Everyone" ], "locale": "en-US", "name": "Micah Silverman", "preferred username": "Micah +okta@afitnerd.com", "sub": "...", "updated at": 1490198843, "zoneinfo": "America/Los Angeles" } Refresh tokens are used to obtain new access tokens. Typically, refresh tokens will be long-lived while access tokens are short-lived. This allows for long-lived sessions that can be killed if necessary. Here's a typical scenario: User logs in and gets back an access token and a refresh token to obtain a new access token and a refresh token the application detects that the access token and gets back an access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token and a refresh token to be application detects that the access token access token and a refresh token to be application detects that the access token acce refresh token expires After the refresh token expires, the user must authenticate again You may be asking: Why do this dance? This approach strikes a balance between user experience and security. Imagine if the user is compromised in some way. Or, their subscription expires. Or, they are fired. At any point, the refresh token can be revoked by an admin. Then, step three above will fail and the user will be forced to (attempt to) establish a new session by authenticate. Identifying Token Types It can be confusing sometimes to distinguish between the different token types. Here's a quick reference: ID tokens carry identity information encoded in the token itself, which must be a JWT Access tokens are used to gain access to resources by using them as bearer tokens Refresh tokens exist solely to get more access tokens are used to gain access to resources by using them as bearer tokens are used to gain access tokens are u types, scopes, and tokens involved. In the next installment, we see OIDC in action! If you want to jump ahead, check out the example at: And, the source code is at: The whole series is live now. Part 2 is here. If you'd like to see other security focused articles like this, you might want to check out our new
security site where we're publishing in-depth articles for infosec people. Page 11 In the first installment of this OpenID Connect (OIDC) series, we looked at some OIDC flow and tokens involved. In this post, we'll dive into the mechanics of OIDC and see the various flows in action. The token(s) you get back from an OIDC flow and the contents of the /userinfo endpoint are a function of the flow type and scopes requested. You can see this live on the OIDC flow test site. Here, you can see this live on the OIDC flow test site. Here, you can see this live on the OIDC flow test site. needs to interact directly with the OpenID Provider (OP)? Do you have middleware, such as Spring Boot or Node is returned from the Authorization Code flow is covered in Section 3.1 of the OIDC spec. The TL;DR is: a code is returned from the /authorization endpoint which can be exchanged for ID and access tokens using the /token endpoint. This is a suitable approach when you have a middleware client connected to an OIDC OP and don't (necessarily) want tokens to ever come back to an end-user application, such as a browser. It also means the end-user application never needs to know a secret key. Here's an example of how this flow gets started using Okta: Let's break that down: Key Value Description Organization URL /oauth2/aus2yrcz7aMrmDAKZ1t7/v1/authorize Default authorization URL /oauth2/aus2yrcz7aMrmDAKZ1t7/v1/authorize Default authorize D response type code The response type indicating code flow scope openid openid scope is required state little-room-greasy-pie Random value to encode into the id token for later validation redirect uri https%3A%2F%2Fokta-oidcfun.herokuapp.com%2Fflow result url-encoded url that the OP redirects to Here it is in the browser: Notice that on the new screen, you are redirected back to the redirect uri originally specified: Behind the scenes, a session is established with a fixed username and password. If you deploy this app on your own (which you can easily do from here),

when you click the link you would be redirected to login and then redirected back to this same page. On the above screenshot, you see the returned code and original state. That code can now be exchanged for an id token and an access token by the middle tier - a Spring Boot application, in this case. This middle tier will validate the state we sent in the authorize request earlier and make a /token request using the Client Secret to mint an access token and id token for the user. Implicit Flow The Implicit Flow is covered in Section 3.2 of the OIDC spec. Essentially, access and ID tokens are returned directly from the /authorization endpoint. The /token endpoint is not used. This is a suitable approach when working with a client (such as a Single Page Application) that you want to interact with the OIDC OP directly. Here's an example of how this flow gets started using Okta: It's almost identical to the authorization code flow, except that the response\_type is either id\_token, token or id\_token+token. Below, we cover exactly what's in these tokens and how it's driven, but remember: an id token encodes identity information and an access token, which enables additional information to be encoded into it. Here's this flow in the browser: You are redirected back to the redirect uri originally specified (with the returned tokens and original state): The application can now verify the id token locally. Use the /introspect endpoint to verify the access token. It can also use the access token. It can also use the access token as a bearer token to hit protected resources, such as the /userinfo endpoint. Hybrid flow is covered in Section 3.3 of the OIDC spec. In this flow, some tokens are returned from the authorization endpoint (/authorize) and others are returned from the token source application to have immediate access to short-lived tokens - such as the id token for identity information, and also want to use a backend service to exchange the authorization code for longer-lived tokens. It's a combination of the authorization code and implicit code flows. You can spot it by looking at the response type it must contain code and one or both of id token and token: Here it is in the browser: You are redirected back to the redirect uri originally specified (with the returned code, tokens and original state): In the next installment, we dig into how to control what's in these tokens, but here's a little taste now: These tokens and original state): In the next installment, we dig into how to control what's in these tokens are produced as a result of hybrid flow with all default scopes enabled. Here's the response from the /userinfo endpoint using the access\_token as a bearer token: { "sub": "00u2yulup4eWbOttd1t7", "name": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "given name": "Okta OIDC", "family name": "Fun", "zoneinfo": "America/Los Angeles", "updated at": 1499922371, "email verified": true } Other OIDC Flows There are two other flows not covered in this post: Client Credentials Flow and Resource Owner Password Credentials. These are both defined in the OAuth 2.0 spec and, as such, are supported by OIDC. Here, we're focusing on flows that these flows support. What information is encoded in the id token, the access token and what information is returned when hitting the protected /userinfo endpoint are a function of the flow type and the scopes requested. In the next post, we dig deeper into this. Token Teardowns In this installment, we looked at OIDC in action. You can experiment with OIDC at You can easily create your own instance of the OIDC tool if you have an Okta tenant. Check mine out at: You can explore the code or just click the friendly purple button to deploy your own instance. In the final installment, we dig into the various types of tokens and how to validate them. The whole series is live now. Part 1 is here. If you enjoyed this, you might also want to check out our new security site where we're publishing lots of in-depth infosec articles. Page 12 In the previous two installments of this OpenID Connect (OIDC) series, we dug deep into the OIDC flow types and saw OIDC in action using a playground found at: . In this third and final installment, we'll look at what's encoded into the various types of tokens and how to control what gets put in them. JWTs, have the benefit of being able to carry information and reduce the number of API calls. Additionally, since they're cryptographically signed, you can verify that they have not been tampered with. The source code that backs the site can be found at: . There are two primary sources for information relating to identity as dictated by the OIDC spec. One source is the information relating to identity as dictated by the OIDC spec. we've chosen to make our access tokens JWTs as well, which provides a third source of information. (You'll see this in many OIDC implementations.) There are a lot of combinations of query parameters that impact what will ultimately be found in returned tokens and the /userinfo endpoint are response\_type. In the following examples, we use only the scopes, openid (required) and email. We'll also work with the implicit flow, since that gives us back tokens immediately Given this request: Notice that response\_type=token will yield us an access token. A particular format is not required in the OIDC spec for access token, we see: { "active": true, "scope": "openid email", "username": "okta\_oidc\_fun@okta.com", "exp": 1501531801, "iat": 1501528201, "sub": "okta\_oidc\_fun@okta.com", "aud": "test", "iss": ", "jti": "AT.upPJqU-Ism6Fwt5Fpl8AhNAdoUeuMsEg]\_VxJ3WJ1hk", "token\_type": "Bearer", "client\_id": "00u2yulup4eWbOttd1t7" } This is mainly resource information, including an expiration (exp) and a user id (uid). If we want to get identity information for the user, we must hit the /userinfo endpoint using the access token as a bearer token. Here's what that looks like using HTTPie: http Authorization: "Bearer ey]hbGciOiJSUzI1NiIsImtpZCI6Ik93bFNJS3p3Mmt1Wk8zSmpnMW5Dc2RNelJhOEV1elY5emgyREl6X3RVRUkifQ..." HTTP/1.1 200 OK ... { "sub": "00u2yulup4eWbOttd1t7", "email": "okta oidc fun@okta.com", "email verified": true } We get back the sub, email and email verified claims. This is because of the default scope=openid+email from the original request. We'll look at some more detailed responses in the scopes section. Let's try another request. We'll look at some more detailed response is a JWT (as required by the OIDC spec) with this information encoded into it: { "sub": "00u2yulup4eWbOttd1t7", "email": "okta\_oidc\_fun@okta.com", "ver": 1, "iss": ", "aud": "1501532056, "jti": "ID.4Mmzy2kj5\_B8nGZ\_PT4dt8-fzu1tA2W3C5dbEF-N6Us", "amr": [ "pwd" ], "idp": "00o1zyyqo9bpRehCw1t7", "nonce": "c96fa468-ca1b-46f0-8974-546f23f9ee6f", "email\_verified": true, "auth\_time": 1501528157 } Notice that we have the sub and emailclaims encoded directly in the JWT. In this type of implicit flow, we have no bearer token to use against the /userinfo endpoint, so the identity information is baked right into the JWT. Finally, let's look at the last type of implicit flow: Here, we are requesting both an id token and an access token in the response. Our access token has the same claims as before. The id token has the following: { "sub": "00u2yulup4eWbOttd1t7", "email": "okta oidc fun@okta.com", "ver": 1, "iss": ", "aud": "0oa2yrbf35Vcbom491t7", "iat": 1501528536, "exp": 1501532136, "jti": "ID.fyybPizTmYLoQR20vlR7mpo8WTxB7JwkxplMQom-Kf8", "amr": [ "pwd" ], "idp": "0001zyyq09bpRehCw1t7", "nonce": "c96fa468-ca1b-46f0-8974-546f23f9ee6f", "auth time": 1501528157, "at hash": "T7ij7o69gBtjo6bAJvaVBQ" } Notice that there's less information in the id token this time (in this case, there's no email verified claim). Because we also requested the access token, it's expected that we will get the rest of the available identity information (based on scope) from the /userinfo endpoint. In this case, it yields the same information as before when we only requested the access token of the available identity information (based on scope) from the /userinfo endpoint. In this case, it yields the same information as before when we only requested the access token of the available identity information as before when we only requested the access token. of information to present: 48 combinations, to be exact. First, I'll enumerate what each scope yields and then we'll look at a few real world examples combining request type and scope. The first thing to note is that the different scopes have an impact on the information encoded in an id token and returned from the /userinfo endpoint. Here's a table of scopes and resultant claims. More information can be found in Section 5.4 of the OIDC Spec scope resultant claims openid (required for all OIDC flows) profile name, middle email verified address address phone number, phone number verified Let's try each of our implicit flows with all the possible (default) scope types. The only difference in the resultant access token to hit the /userinfo endpoint, I get back more information: http Authorization: "Bearer eyJhbGciOiJSUzI1NiIsImtpZCI6Ik93bFNJS3p3Mmt1Wk8zSmpnMW5Dc2RNelJhOEV1elY5emgyREl6X3RVRUkifQ..." HTTP/1.1 200 OK ... { "sub": "00u2yulup4eWbOttd1t7", "name": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale":
"en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "Okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "okta OIDC Fun", "locale": "en-US", "email": "okta oidc fun@okta.com", "preferred username": "okta OIDC Fun", "locale": "en-US", "email": "en-U "okta\_oidc\_fun@okta.com", "given\_name": "Okta OIDC", "family\_name": "Fun", "zoneinfo": "America/Los Angeles", "updated\_at": 1499922371, "email\_verified": true } Note: While it's not the complete list of claims defined from profile scope, it's all the claims for which my user in Okta has a value. Let's try just the id\_token implicit flow (still with all the default scopes): Here's what's encoded into the id token I get back: { "sub": "00u2yulup4eWbOttd1t7", "iat": 15015352222, "exp": 1501535822, "jti": "ID.Zx8EclaZmhSckGHOCRzOci2OaduksmERymi9-ad7ML4", "iat": 1501532222, "exp": 1501535822, "jti": "ID.Zx8EclaZmhSckGHOCRzOci2OaduksmERymi9-ad7ML4", "iat": 1501535822, "jti": "ID.Zx8EclaZmhSckGHOCRZOci2OaduksmERymi9-ad "amr": [ "pwd" ], "idp": "0001zyyqo9bpRehCw1t7", "nonce": "c96fa468-ca1b-46f0-8974-546f23f9ee6f", "preferred\_username": "Okta\_oidc\_fun@okta.com", "given\_name": "Fun", "zoneinfo": "America/Los\_Angeles", "updated\_at": 1499922371, "email\_verified": true, "auth\_time": 1501528157 } All the (available) identity name": "Okta\_oidc\_fun@okta.com", "given\_name": "Fun", "zoneinfo": "America/Los\_Angeles", "updated\_at": 1499922371, "email\_verified": true, "auth\_time": 1501528157 } All the (available) identity name": "Okta\_oidc\_fun@okta.com", "given\_name": "Okta\_oidc\_fun@okta.com", "given\_name": "Okta\_oidc\_fun@okta.com", "given\_name": "Okta\_oidc\_fun@okta.com", "given\_name": "Okta\_oidc\_fun@okta.com", "given\_name": "Okta information is encoded right into the token, since I don't have a bearer token to hit the /userinfo endpoint with. Finally, let's try the last variant of the Implicit Flow: response\_type=id\_token+token: In this case, we have some of the claims encoded into the id\_token: { "sub": "00u2yulup4eWbOttd1t7", "name": "Okta OIDC Fun", "email". "okta\_oidc\_fun@okta.com", "ver": 1, "iss": ", "aud": "0oa2yrbf35Vcbom491t7", "iat": 1501532304, "exp": 1501535904, "jti": "ID.1C2NQext2hM0iJy55cLc\_Ryc45urVYC1wJ0S-KebkpI", "amr": [ "pwd"], "idp": "00o1zyyqo9bpRehCw1t7", "nonce": "c96fa468-ca1b-46f0-8974-546f23f9ee6f", "preferred\_username": "okta\_oidc\_fun@okta.com", "auth\_time" 1501528157, "at\_hash": "GB5O9CpSSOUSfVZ9CRekRg", "c\_hash": "mRNStYQm-QU4rwcfv88VKA" } If we use the resultant access token to hit the /userinfo endpoint, in this case, we get back: http Authorization:"Bearer eyJhbGciOiJSUzI1NiIsImtpZCI6Ik93bFNJS3p3Mmt1Wk8zSmpnMW5Dc2RNelJhOEV1elY5emgyREl6X3RVRUkifQ..." HTTP/1.1 200 OK ... { "sub": "00u2yulup4eWbOttd1t7", "name": "Okta OIDC Fun", "locale": "en-US", "email": "okta\_oidc\_fun@okta.com", "given\_name": "Fun", "zoneinfo": "America/Los\_Angeles", "updated\_at": 1499922371, "email\_verified": true } This rounds out all the identity information that was requested in the scopes. Custom Scopes and Claims The OIDC spec accommodate custom scopes and claims. The ability to include custom scopes and claims. The ability to include custom scopes and claims in a token (which is cryptographically verifiable) is an important capability for identity providers. Okta's implementation providers. Okta's implementation providers and claims in a token (which is cryptographically verifiable) is an important capability for identity providers. Authorization Server's Claims tab: Clicking the "Add Claim" button brings up a dialog: In the above screenshot, the custom claim is defined using Okta's Expression language is a flexible way to describe rules for building a property to include (or not) in custom claims. Using the implicit flow with response type=id token and scope=openid+profile, we now get back an id token with these claims encoded in it: { "sub": "00u2yulup4eWbOttd1t7", "iat": 1501533536, "exp": 1501537136, "jti": "ID.TsKlBQfGmiJcl2X3EuhzyyLfmzqi0OCd66rJ3Onk7FI", "amr": [ "pwd" ], "idp": "00u2yulup4eWbOttd1t7", "iat": 1501533536, "exp": 1501537136, "jti": "ID.TsKlBQfGmiJcl2X3EuhzyyLfmzqi0OCd66rJ3Onk7FI", "amr": [ "pwd" ], "idp": "00u2yulup4eWbOttd1t7", "iat": 1501533536, "exp": 1501533536, "exp": 1501533536, "exp": 1501533536, "exp": 1501537136, "jti": "ID.TsKlBQfGmiJcl2X3EuhzyyLfmzqi0OCd66rJ3Onk7FI", "amr": [ "pwd" ], "idp": "00u2yulup4eWbOttd1t7", "iat": 1501533536, "exp": 1501533536, "exp": 1501533536, "exp": 1501533536, "exp": 1501537136, "jti": "ID.TsKlBQfGmiJcl2X3EuhzyyLfmzqi0OCd66rJ3Onk7FI", "amr": [ "pwd" ], "idp": "00u2yulup4eWbOttd1t7", "iat": 1501533536, "exp": 1501533536, "exp": 1501537136, "jti": "ID.TsKlBQfGmiJcl2X3EuhzyyLfmzqi0OCd66rJ3Onk7FI", "amr": [ "pwd" ], "idp": "00u2yulup4eWbOttd1t7", "iat": 1501533536, "exp": 1501533536, "exp "0001zvvgo9bpRehCw1t7", "nonce": "c96fa468-ca1b-46f0-8974-546f23f9ee6f", "auth time": 1501528157, "at hash": "hEjyn3mbKjuWanuSAF-z4Q", "full name claim present in the id\_token. Verifying Tokens Access tokens can be verified by hitting the /introspect endpoint. For an active token, you get a response like this: http --auth : -f POST \ token=ey]hbGciOiJSUzI1NiIsImtpZCI6Ik93bFNJS3p3Mmt1Wk8zSmpnMW5Dc2RNel]hOEV1elY5emgyREl6X3RVRUkifQ... HTTP/1.1 200 OK ... { "active": true, "aud": ", "client id": "xdgqP32nYN148gn3gJsW", "exp": 1498517509, "fullName": "Micah Silverman", "iat": 1498513909, "iss": ", "jti": "AT.JdXQPAuh JTqhspCL8nLe2WgbfjcK -jmlp7zwaYttE", "scope": "openid profile", "sub": "micah+okta@afitnerd.com", "token\_type": "Bearer", "uid": "00u9vme99nxudvxZA0h7", "username": "micah+okta@afitnerd.com" } Since it requires the OIDC client ID and secret, this operation would typically be done in an application server where it's safe to have those credentials. You would not want something like an end-user web or mobile application to have access to the OIDC client secret. If the token parameter is invalid or expired, the /introspect endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK is a JSON (\ token=bogus HTTP/1.1 200 OK ... { "active": false } ID tokens can be verified using the JWK endpoint. JWK endpoint at the JWK endpoint at th data structure that represents a crypto key. The JWK endpoint is exposed from the OIDC "well known" endpoint": ", ... "introspection endpoint": ", ... "introspection endpoint": ", ... "issuer": endpoints, such as /userinfo and /authorize, should look familiar by now. The one we're interested in is the /keys endpoint shown in jwks\_uri. http HTTP/1.1 200 OK ... { "keys": [ { "alg": "RS256", "e": "AQAB", "kid": "cbkhWG0YmFsGiNO1LEkWSEszDCTNfwvJPpXxuVf\_kX0", "kty": "RSA", "n": "g2XQgdyc5P6F4K26ioKiUzrdgfy90eBgIbcrKkspKZmzRJ3CIssv69f1ClJvT784J-...", "use": "sig" } ] } Notice the kid claim. It matches the kid claim in the header from our id\_token: { "typ": "JWT", "alg": "RS256", "kid": "cbkhWG0YmFsGiNO1LEkWSEszDCTNfwvJPpXxuVf\_kX0" } We can also see that the algorithm used is RS256. Using the public key found in the n claim along with a security library, we can confirm that the ID token has not been tampered with. All of this can be done safely on an end-user SPA, mobile app, etc. Here's a Java example that uses the claims from the jwks\_uri above to verify an id\_token: java -jar target/jwk-token-verifier-0.0.1-SNAPSHOT-spring-boot.jar \ eyJhbGciOiJSUzI1NiIsImtpZCI6Ik93bFNJS3p3Mmt1Wk8zSmpnMW5Dc2RNel... \ g2XQgdyc5P6F4K26ioKiUzrdgfy90eBgIbcrKkspKZmzRJ3CIssv69f1ClJvT784J-... \ AQAB Verified Access Token { "header" : { "alg" : "RS256", "kid" : "cbkhWG0YmFsGiNO1LEkWSEszDCTNfwvJPpXxuVf kX0" }, "body" : { "ver" : 1, "jti" "AT.LT9cRL Kzd3T8Izw ONZxHJ5xGBPD0m13iiEIDK Nbw", "iss" : ", "aud" : "test", "iat" : 1501533536, "exp" : 1501537136, "cid" : "0oa2yrbf35Vcbom491t7", "signature" : "ZV 9tYxt4v4bp9WEEDu038b7v OHsbMZw13daR1s5 tI56oayBq]lnqf-..." } If any part of the id\_token JWT had been tampered with, you would see this instead: io.jsonwebtoken.Signature does not match locally computed signature. JWT signature does not match locally component of OIDC. It allows for a high degree of confidence that the token has not been tampered in any way. And, because of that, information contained within - such as expiration - can be safely enforced. How I Learned to Love OpenID Connect When OIDC was first released and early implementers,
such as Google, adopted it, I thought: "I just got used to OAuth 2.0. Why do I have to learn a new thing that rides on top of it?" It took some time, but here is what I consider to be the important takeaways: OIDC formalizes a number of things left open in OAuth 2.0. Things like: specific token formats (id\_token) and specific scopes and claims. There's explicit support for Authentication and Authorization. OAuth 2.0 was always presented purely as an authorization framework, but people would get confused with certain flows that allowed for authentication. There's a clear separation between identity (id token and /userinfo) and access to keen). The different flows provide clean use case implementations for mobile apps, SPAs, and traditional web apps. It's inherently flexible. It's easy to provide custom scopes and claims and to dictate what information should be encoded into tokens beyond the default specification. All the code used in this series can be found on github. You can use the OIDC spec can be found here. And you can learn more about OAuth 2.0 at oauth.com. The whole series is live now. Part 1 is here. If you're looking for other security pieces. Page 13 You're built a microservices architecture with Spring Boot and Spring Cloud. You're happy with the results, and you like how it adds resiliency to your application. You're also pleased with how it scales and how different teams can deploy microservices locked down too, or are they just behind the firewall? This tutorial shows you how you can use Spring Security, Okta, and a few Java libraries to secure everything, so even your microservices architecture. Not only that, but I'll show you how to secure everything, so even your microservices architecture. and turn it into a Spring Security User. This tutorial builds off Build a Microservices Architecture for Microbrews with Spring Boot. A simple microservices architecture with Spring Boot. A simple microservices architecture with Spring Boot. A simple microservices architecture for Microbrews with Spring Boot. A simple microservices architecture with Spring Boot. A simpl and Juiser, a library created by Les Hazlewood. Juiser is independent and open source, and is not tied to a particular identity provider. Once you've completed this tutorial, you'll have Spring Security locking things down, and Okta providing authentication and JWT validation. In this tutorial, you'll have Spring Security locking things down, and Okta provider. and related projects. To add security with Okta, you'll have to create two applications in your developer console. The first will be a "Native" application that supports the Stormpath Java SDK, and OAuth grant types authorization code, refresh token, and resource owner password. This type of application is typically reserved for native mobile applications, but it also includes the Stormpath Java SDK. This is because the Stormpath SDK was retrofitted to work with Okta, and not built specifically for the Okta API, per se. For the Angular client, you'll need a second "SPA" application. To begin, you'll need to clone the aforementioned article's completed project. git clone -b v1.0 Create an Okta Developer account, and create a "Native" application Name: My Test App Login redirect URIs: After URIs: After your application has been created, you still have a few settings you need to change: On the General tab, click Edit on the General Settings panel Select Use Client Authentication and click Save Copy and save the Client ID for your application At this point, your application's settings should look as follows: You'll also need to create an API token: On the top menu, click on API > Tokens Click Create Token Important: You will need to remember this token value, so copy/paste it somewhere safe. After completing these steps, you should have the information you need to set the following environment variables. export OKTA APPLICATION ID={clientId} export OKTA APPLICATION ID={cli Support to the Edge Service NOTE: I'm using Stormpath's Java SDK in this example. It has been updated to work with Okta's API. If you'd like to see how to do this same tutorial using Spring Security and its OAuth support, please Secure a Spring Microservices Architecture with OAuth 2.0. The edge-service application handles the routing to the backend beer-catalog-service, so it's the best place to start securing things. Add the Stormpath.spring stormpath-bom 2.0.4-okta pom import Then add a dependency for Stormpath's Zuul integration. com.stormpath-spring stormpath-zuul-spring cloud-starter Add the following properties and values to edge-server/src/main/resources/application.properties.server.use-forward-headers=true zuul.routes.home.path=/home zuul.routes.home.url= stormpath.web.cors.allowed.originUris= stormpath.zuul.account.header.jwt.key.resource=classpath:rsatest.priv.pem # This is just one example of a key ID - anything that the origin server can make sense of to lookup # the corresponding public key is fine. Here we use the public key file name. stormpath.zuul.account.header.jwt.key.id=rsatest.pub.pem Copy the rsatest.\* files from the Stormpath Zuul example project, or create new ones using the following command: openssl genrsa -out rsatest.priv.pem 2048 Generate the private key's corresponding rsatest.pub.pem After copying (or generating), both rsatest.priv.pem and rsatest.pub.pem files should be in edge-service/src/main/resources. Add Juiser to the Beer Catalog Service Juiser is a small Java library that automates token authentication during an HTTP request. In this example, Juiser to read the X-Forwarded-User header and creates a Spring Security User for you. For Juiser to the Beer Catalog Service Juiser is a small Java library that automates token authentication during an HTTP request. public key (rsatest.pub.pem) from edge-service/src/main/resources to beer-catalog-service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. Then add the following dependencies to the Beer Catalog Service/src/main/resources. The spring-boot-starter-security org.springframework.security spring-security-web authentication is working. package com.example.beercatalogservice; import org.juiser.model.User; import org.springframework.web.bind.annotation.GetMapping; @Controller public class HomeController { private final User user; public HomeController(User user) { this.user = user; } @GetMapping("/home") public String howdy(Model model) { model.addAttribute("user", user); return "home"; } } NOTE: There is an issue with Juiser 1.0.0 that it won't initialize if you don't have at least one @Controller in your project. Create a home.html template in beer-catalogservice/src/main/resources/templates/home.html and populate it with the following code. th { text-align: left; } td { white-space: nowrap; } td:first-child { font-family: "Courier", monospace; font-size: 0.9em; color: #343434; } Hello Joe! Login User Properties Name Value anonymous authenticated href id name givenName middleName familyName nickname username profile picture website email email/Verified gender birthdate zoneInfo phoneNumber verified createdAt updatedAt Add the following properties to beer-catalog-service/src/main/resources/application.properties to configure Juiser. server.use-forward-headers=true juiser.header.jwt.key.resource=classpath:rsatest.pub.pem Create a SecurityConfig.java class in the same package com.example.beercatalogservice; import org.springframework.context.annotation.Configuration; import org.springframework.security.config.annotation.web.builders.HttpSecurity; import org.springframework.securityConfigurerAdapter { @Override protected void configure(HttpSecurity http) throws Exception { http.authorizeReguests().anyReguest().fullyAuthenticated(); } } Add ReguestInterceptor for Feign The @FeignClient used to talk to beer-catalog-service is not aware of the X-Forwarded-User header. To make it aware, create a ForwardedAccountReguestInterceptor class in the same directory as EdgeServiceApplication, package org.springframework.web.context.request.ServletRequest; import javax.servlet.http.HttpServletRequest; import javax LoggerFactory.getLogger(ForwardedAccountRequestInterceptor.class); private final Resolver valueResolver; } @Override public void apply(RequestTemplate template) { if (template.headers().containsKey(ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME)) { LOGGER.warn("The X-Forwarded-User has been already set"); } else { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest request = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest request = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account",
ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest request = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); HttpServletRequest = ((ServletRequestAttributes)) { LOGGER.debug("Constructing Header { } for Account", ForwardedAccountHeaderFilter.DEFAULT\_HEADER\_NAME); { RequestContextHolder.getRequestAttributes()).getResponse = ((ServletResponse = ((ServletRequestAttributes)); } } Register it as a @Bean in EdgeServiceApplication. import org.springframework.context.annotation.Bean; import feign.RequestInterceptor; import com.stormpath.sdk.servlet.http.Resolver; ... public class EdgeServiceApplication { public static void main(String[] args) { SpringApplication.run(EdgeServiceApplication.class, args); } @Bean public RequestInterceptor (accountRequestInterceptor (accountRequestInterceptor (accountRequestInterceptor); } } While you're modifying EdgeServiceApplication, change the HystrixCommand in BeerController to make Hystrix execute on the calling thread (so it's aware of the security context). import com.netflix.hystrix.contrib.javanica.annotation.HystrixProperty; ... @HystrixCommand(fallbackMethod = "fallback", commandProperties = { @HystrixProperty(name="execution.isolation.strategy", value="SEMAPHORE") }) NOTE: There is an issue with the Stormpath Zuul Starter where it doesn't work with Spring Cloud Edgeware.SR1. Change edge-service/pom.xml to have Dalston.RELEASE to workaround this issue. Verify Secure Communication between the edge-service and beer-catalog-service: cd eureka-service: cd eureka-service: cd eureka-service: cd eureka-service: cd eureka-service: cd eureka-service: cd eureka-service ./mvnw spring-boot:run In another terminal window, start edge-service: cd edge-service: cd eureka-service: cd eureka-service: cd eureka-service ./mvnw spring-boot:run In a new terminal window, start edge-service: cd edge-service: cd edge-service: cd edge-service: cd edge-service: cd edge-service ./mvnw spring-boot:run In another terminal window, start edge-service: cd edge-ser Open your browser and navigate to . You should see a login page, prompting for your credentials. This page is served up from the stormpath-zuul-spring-cloud-starter using Thymeleaf. Spring Boot auto-activates Thymeleaf. Spring Boot auto-activates Thymeleaf. button to delete the cookies in your browser and end your session. To use Okta's Sign-In Widget, you'll need to create an additional app in Okta by going to the Developer Console and navigating to Applications and click on the Add Application button. Select SPA and click Next. On the next page, specify as a Base URI, Login redirect URI, and Logout redirect URI. Click Done and you should see settings like the following. Install @okta/okta-signin-widget --save Add the widget's CSS to src/styles.css: @import '~@okta/okta-signin-widget/dist/css/okta-signin-widget/dist/css/okta-signin-widget/dist/css/okta-signin-widget/dist/css/okta-signin-widget/dist/css/okta-signin-widget/dist/css/okta-signin-widget/; import \* as OktaSignIn from '@okta/okta-signin-widget'; Create client/src/app/shared/okta-signin-widget/dist/css/okta-signin-widget'; import \* as OktaSignIn from '@okta/okta-signin-widget'; Create client/src/app/shared/okta-signin-widget'; Create client/s @Injectable() export class OktaService { widget; constructor() { this.widget = new OktaSignIn({ baseUrl: 'https://{yourOktaDomain}', clientId: '{clientId}', authParams: { issuer: 'default', responseType: ['id token', 'token'], scopes: ['openid', 'email', 'profile'] } }); } getWidget() { return this.widget; } getIdToken() { return this.widget.tokenManager.get('idToken'); } getAccessToken() { return this.widget.tokenManager.get('accessToken'); } Make sure to replace {yourOktaDomain} and {clientId} in the above code. Add OktaService as a provider to client/src/app/app.module.ts. import { OktaService } from './shared/okta.service'; @NgModule({ ... providers } from '... providers } from '... providers } from '... providers & from '... providers & from '... providers } from '... providers & from '... prov [OktaService], bootstrap: [AppComponent] }) export class AppModule { } Modify client/src/app/shared/beer/beer.service.ts to read the access token and set it in an Authorization header when it exists. import { Injectable } from '@angular/core'; import { Observable } from '@angular/core'; import } 'rxjs/Observable'; import { OktaService } from '../okta/okta.service'; @Injectable() export class BeerService { constructor(private http: HttpClient, private oktaService) { } getAll(): Observable { let headers: HttpHeaders = new HttpHeaders(); if (this.oktaService.getAccessToken()) { const accessToken = new HttpHeaders = new HttpHeaders(); if (this.oktaService.getAccessToken()) { const accessToken = new HttpHeaders = new HttpHeaders(); if (this.oktaService.getAccessToken()) { const accessToken = new HttpHeaders(); if (this.oktaService.getAccessToken()) { const accessToken = new HttpHeaders(); if (this.oktaService) { } etable(); if (this.oktaService.getAccessToken()) { const accessToken() } etable(); if (this.oktaService) { } etable(); if (this.oktaService) { } etable(); if (this.oktaService); etable(); etabl this.oktaService.getAccessToken(); // headers is immutable, so re-assign headers = headers.append('Authorization', accessToken.tokenType + ' ' + accessToken.accessToken); } Modify app.component.html to add a placeholder for the widget and a section to show the user's name and a logout button. Welcome to {{title}}! Welcome {{user?.name}}! Logout You'll notice the user variable in the HTML. To resolve this, you need to change your src/app/app.component.ts so it renders the Sign-In Widget. Angular's ChangeDetectorRef is used to notify Angular when things have changed and rendering needs to process changed variables. import { ChangeDetectorRef, Component, OnInit } from '@angular/core'; import { OktaService } from './shared/okta.service'; @Component.css'] }) export class AppComponent implements OnInit { title = 'app'; user; signIn; constructor(private oktaService'; @Component.css'] }) OktaService, private changeDetectorRef: ChangeDetectorRef) { this.signIn = oktaService.getWidget(); } showLogin() { this.signIn.renderEl({el: '#okta-signin-container'}, (response.status === 'SUCCESS') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { response.forEach(token => { if (token.idToken) { this.signIn.tokenManager.add('idToken', token); this.user = 'Success') { this.signIn.tokenManager.add('idToken', token); this.user = 'Success'} { this.signIn.tokenManager.add('idToken', token); this.user = 'Success'} { this.signIn.tokenManager.add('idToken', token); this.user = 'Success'} { this.signIn.tokenManager.add('idToken' this.getUser(token); } if (token.accessToken); } if (token.accessToken); } if (token.accessToken); } ); } getUser(token); } if (token.accessToken); } ); } getUser(token); } if (token.accessToken); } i = { if (response.status !== 'INACTIVE') { const token = this.getUser(token); this.changeDetectorRef.detectChanges(); } } ] In order for the { this.showLogin(); } }; } ] In order for the { this.showLogin(); } } ] [ this.showLogin(); } ] ] ] [ this.showLogin(); } ] ] ] [ this.showLogin(); } ] ] ] [ this.showLogin(); ] ] ] ] [ this.showLogin(); ] ] ] ] ] [ this.showLogin(); ] ] ] ] [ this.showLogin(); ] ] ] ] [ this.showLogin(); ] ] ] ] ] ] ] [ this.showLogin(); ] ] ] ] ] [ this.showLogin(); ] ] ] ] ] ] ] ] [ this.showLogin(); ] ] ] ] ] ] ] [ this.showLogin(); ] ] ] ] ] ] [ this.showLogin(); ] ] ] ] ] ] ] [ this.showLogin(); ] ] ] ] ] ] ] [ this.showLogin(); ] ] ] ] [ this.showLogin(); ] ] ] ] ] [ this.showLogin(); ] ] ] [ this.showLogin(); ] ] ] ] [ this.showLogin(); ] ] ] ] [ this.showLogin(); ] ] ] [ this.showLogin(); ] ] ] [ this.showLogin(); ] [ this.showLogin(); ] [ this.showLogin(); ] [ this.showLogin(); ] ] [ this.showLogin(); ] [
this.showLogin(); ] [ this.showLogin(); ] [ this.showLogin(); ] ] [ this.sho BeerListComponent (at src/app/beer-list.component.ts) to detect that you've logged in, you need to use add a constructor dependency on ChangeDetectorRef and invoke its detectChanges() method when you set the giphyUrl property on each beer. import { BeerService, GiphyService } from '../shared'; @Component.({ selector: 'app-beer-list.component.html', styleUrls: ['./beer-list.component.ttml', styleUrls: ['./beer-list.component.ttml', styleUrls: ['./beer-list.component.html', styleUrls: ['./beer-list.component.ttml', styleUrls: [ GiphyService, private changeDetectorRef: ChangeDetectorRef: { } ngOnInit() { this.beerService.getAll().subscribe(url => { beer.giphyUrl = url; this.changeDetectorRef.detectChanges(); }); } }, error => console.log(error) ) } } Verify Authentication Works Start the client with npm start, navigate to , and you should see a login form like the following. NOTE: If it logs you in automatically, this is likely because you have cookies, or try an incognito window. If you want to adjust the style of the form, so it isn't right up against the top toolbar add the following to client/src/styles.css. #okta-signin-container { margin-top: 25px; } You should be able to log in, see a welcome message, as well as a logout button. Learn More This article showed you how to use Spring Security, and Juiser, you can ensure your backend services communicate securely. The source code for this tutorial is available on GitHub, in the "okta" branch. git clone git checkout okta Learn more about Okta and its APIs at developer.okta.com. If you have questions about this tutorial, please hit me up on Twitter @mraible or post a question to Stack Overflow with an "okta" tag. Update: To learn how to lock down this application with Spring Security and OAuth, see Secure a Spring Microservices Architecture with Spring REST endpoints, and if you're a Java shop you've probably tried out JAX-RS, Spring REST, or both. But is one better than the other? In this post I'll go over the differences between the two using basically the same code for an apples to apples to apples to apple things focused, I'll leave the Maven dependencies out of this post. You can browse the full source on GitHub, the pom files should be self explanatory: one for JAX-RS, another for Spring. First up, we need to get the common bits out of the way. A simple model and DAO (Data Access Object) will be used in all of the examples to register and manage Stormtrooper objects. public class Stormtrooper { private String id; private String species; private String type; public Stormtrooper() { // empty to allow for bean access } public Stormtrooper() { // empty to allow // bean accessor methods The Stormtrooper object contains an id and a few other attributes: planetOfOrigin, species, and type. The DAO interface is just as simple, with the basic CRUD methods and an additional list method: public interface is just as simple, with the basic CRUD methods and an additional list method. stormtrooper); Stormtrooper updateStormtrooper(String id, StormtrooperDao, which generates 50); } The actual implementation of the StormtrooperDao, which generates 50 random Stormtroopers. Try Spring Now that we have the common bits out of the way, we can get into the meat of our SpringBootApplication public class SpringB public static void main(String[] args) { SpringApplication.run(SpringBootApplication.run(SpringBootApplication and classpath scanning of components @Bean binds an instance of DefaultStormtrooperDao to the StormtrooperDao interface The main method starts the application uses the SpringApplication.run() helper method to bootstrap the application Spring Controller. We will use this class to map our DAO to incoming HTTP requests. @RestController @RequestMapping("/troopers") public class String id) throws NotFoundException { Stormtrooper stormtrooper = trooperDao.getStormtrooper(id); if (stormtrooper(ic); } return stormtrooper; } @PostMapping public Stormtrooper createTrooper(@RequestBody Stormtrooper trooper) { return trooperDao.addStormtrooper(trooper); } @PostMapping("/{id}") public Stormtrooper updatedTrooper(id, updatedTrooper); } @DeleteMapping("/{id}") @ResponseStatus(value = HttpStatus.NO\_CONTENT) public void deleteTrooper(@PathVariable("id") String id) { trooperDao.deleteStormtrooper(id); } } Let's break this down: @Controller is a convenience annotation for both @Controller and @ResponseBody which marks this class as a web component discovered during classpath scanning. An @RequestMapping annotation at the the class level defines the base path mapping used for any other RequestMapping annotations in this class. In this class will start with the URL path /troopers. @PostMapping("/{id}") public @ResponseBody Stormtrooper updateTrooper(@PathVariable("id") String id, @RequestBody Stormtrooper updatedTrooper) throws NotFoundException { return trooperDao.updateStormtrooper(id, updatedTrooper); } The PostMapping annotation which has many options, this example uses a small subset: path = "/{id}" used in conjunction with @PathVariable("id") maps the {id} part of the URL path to the given method argument - Example URL: /troopers/FN-2187 value = HttpStatus.NO\_CONTENT sets the expected HTTP response code, in this case a 204 Method parameters annotated with @RequestBody will be deserialize from the HTTP response code. to HTTP response using the @ResponseBody annotation (or simply by using @RestController), which will also bypass any MCV templates. In this code block the updateTrooper(] method accepts HTTP POST requests made to /trooper/{id} and contain a serialized Stormtrooper (JSON). If the request path was /troopers/FN-2187, the id portion of the path would be assigned to the method's id parameter. An updated Stormtrooper object is returned and serialized to the HTTP response. In the example above we are simply using a POST for both the create and update methods. To keep the example above we are simply using a POST for both the create and update methods. be a PUT. Take a look at this blog post to read more about when to use PUT vs POST. Run the Spring-boot:run, make requests to the server. To get get a list of all the Stormtroopers just make a request to /troopers \$ curl HTTP/1.1 200 Content-Type: application/json;charset=UTF-8 Date: Tue, 08 Nov 2016 20:33:36 GMT Transfer-Encoding: chunked X-Application-Context: application [ { "id": "FN-0984", "planetOfOrigin": "Unknown", "species": "Human", "type": "Basic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Basic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Basic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant",
"species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type": "Aquatic" }, { "id": "FN-0984", "planetOfOrigin": "Coruscant", "species": "Human", "type" "FN-1253", "planetOfOrigin": "Tatooine", "species": "Unidentified", "type": "Sand" }, ...] To get a single Stormtrooper, use its ID: \$ curl HTTP/1.1 200 Content-Type: application/context: application/; "id": "FN-2187", "planetOfOrigin": "Unknown", "species": "Human", "type": "Basic" } Pretty easy, right? Now you can stop the server with a Ctrl-C and move on to the next example, all we're going to change is the annotations on the StormtroooperController class. Since JAX-RS is an API spec you need to pick an implementation, we will use Jersey for this example. While it's possible to create a JAX-RS application with no direct dependencies on a specific JAX-RS implementation, it would make for a more verbose example. I picked Jersey for a couple reasons, mostly though it was because I already knew how get simple dependency injection working without jumping through any hoops, we are comparing this to Spring after all. Apache Shiro has an example that runs the same code on Jersey, RestEasy, and Apache CXF, if you're interested in seeing a portable example. This example also differs a bit from the Spring Boot was a single JAR. Packing this example in an executable jar is possible, but outside the scope of this post A JAX-RS equivalent to a SpringBootApplication, Resource Config, adds a few handy utility methods. The following snippet configures classpath scanning to detect our individual resource classes, and bind a DefaultStormtrooperDao instance to the StromtrooperDao interface. @ApplicationPath("/") public class JaxrsApp extends ResourceConfig { public JaxrsApp() { // scan the resources package().getName() + ".resources"); // use @Inject to bind the StormtrooperDao register(new AbstractBinder() { @Override protected void configure() { bind(stormtrooperDao()).to(StormtrooperDao.class); } }); } private StormtrooperDao(); } One other thing to point out, in the above class the @ApplicationPath annotation marks this class as a JAX-RS Application bound to a specific url path, in our case to match the Spring example above we will just use the root path: /. Each resource detected in the resources package will be appended to this base path. The JAX-RS resource implementation looks very similar to the Spring version above (renamed to StormtroooperResource, to match naming conventions): @Path("/troopers") @Produces("application/json") public class StormtrooperResource { @Inject private StormtrooperCao, @Path("/{id}") @GET public Stormtrooper == null) { throw new NotFoundException { Stormtrooper == null { throw new NotFoundExcepti NotFoundException(); } return stormtrooper; } @POST public Stormtrooper createTrooper(Stormtrooper trooper) { return trooperDao.addStormtrooper (pathParam("id") String id, Stormtrooper updatedTrooper) throws NotFoundException { return trooperDao.addStormtrooper("id") String id, Stormtrooper updatedTrooper) throws NotFoundException { return trooperDao.addStormtrooper("id") String id, Stormtrooper updatedTrooper("id") String id, Stormtrooper updatedTrooper) throws NotFoundException { return trooperDao.addStormtrooper("id") String id, Stormtrooper updatedTrooper("id") String id, Stormtrooper updatedTrooper ("id") String id, Stormtrooper updatedTrooper ("id") String id, Stormtrooper updatedT trooperDao.updateStormtrooper(id, updatedTrooper(id); } @GET public Collection listTroopers(); } } To break down this example a bit, we first have the class deceleration: @Path("/troopers"); } To break down this example a bit, we first have the class deceleration: @Path("/troopers"); } @OELETE public void deleteTrooper(id); } @GET public Collection listTroopers(); } } @Produces("application/json") public class StormtroooperResource { Similar to the Spring example above the @Path at the class level means each annotation defines the default response content type (unless overridden by an annotation on another method). Unlike the Spring example where a @RequestMapping annotation defined the path, method, and other attributes of the request, in a JAX-RS resource each attribute uses a separate annotation. Similar to above if we break down the updateTrooper() method: @Path("/{id}") @POST public Stormtrooper updateTrooper(@PathParam("id") String id, Stormtrooper updatedTrooper) throws NotFoundException { return trooperDao.updateStormtrooper(id, updatedTrooper); } We see that @Path("/{id}") along with @PathParam("id") along with @PathParam("id") along with @PathCareful ("/{id}") along with @PathCareful ("//{id}") along with @PathCareful ("// not need extra annotations, they are automatically serialized into JSON due to the @Produces("application/json") annotation on this class. Run the JAX-RS Example Can be started from the jersey directory, using the maven command: mvn jetty:run. Making the same two requests as above, we can list all of the troopers with a GET request to the base resource: \$ curl HTTP/1.1 200 OK Content-Length: 3944 Content-Type: application/json Date: Tue, 08 Nov 2016 21:57:55 GMT Server: Jetty(9.3.12.v20160915) [ { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Human", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Nikto", "type": "Basic" }, { "id": "FN-2064", "planetOfOrigin": "Naboo", "species": "Naboo", " "Sand" }, { "id": "FN-0069", "planetOfOrigin": "Hoth", "species": "Twi'lek", "type": "Jump" }, ... Or again to a GET to a specific resource: \$ curl HTTP/1.1 200 OK Content-Length: 81 Content-Type: application/json Date: Tue, 08 Nov 2016 22:00:02 GMT Servers Jetty(9.3.12.v20160915) { "id": "FN-2187", "planetOfOrigin": "Unknown", "species": "Human", "type": "Basic" } Now we have seen basically the same code run in both Spring and JAX-RS applications by simply changing the annotations. I like the JAX-RS annotations better, they're more concise. That said, why choose between the two? Jersey and RestEasy both support Spring (along with Guice and CDI/Weld). Let's create a third example combining the two JAX-RS and Spring – So Happy Together For this example we need three classes are identical to the previous versions, the only difference being the Jersey configuration class: @Component public class JerseyConfig { public JerseyConfig { pub the @Configuration annotation which is used to mark this class managed by Spring. All that is left, is to instruct Jersey to scan the resources package again, the rest is handled for you (see what I did there?!). From the spring-jaxrs directory, this example can be started with the same mvn spring-boot:run command. Spring to JAX-RS Cheat Sheet To help you navigate between the world of Spring and JAX-RS here is a quick cheat sheet. This is not an exhaustive list, but it does include the most common annotations. Spring Annotation @RequestMapping(path = "/troopers") @PostMapping @POST @PutMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @POST @PutMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @POST @PutMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @POST @PutMapping @POST @PutMapping @GET @DeleteMapping(path = "/troopers") @PostMapping @POST @PutMapping @GET @DeleteMapping @PostMapping @POST @PutMapping @POST @PutMapping @GET @DeleteMapping @PostMapping @POST @PutMapping @POST @PutMapping @POST @PutMapping @POST @PutMapping @PostMapping @Pos @DELETE @ResponseBody N/A @RequestBaram("xyz") @RequestParam("xyz") @Req @Consumes("application/json") When Should You Use JAX-RS over Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion it breaks down like this: If you're already a Spring Rest? In my opinion all the spring R side is not
part of the JAX-RS spec (though it is supported with extensions). I hacked up a Thymeleaf view for Jersey once, but I think Spring Boot application, isn't exactly comparing a Spring Boot application and an WAR packaged application and Jersey. is probably the closest thing to a Spring Boot app. Hopefully this post gave you a bit more background so you can do your own comparison. If you have any questions hit me up on Twitter @briandemers! Want to learn more about securing your Spring or JAX-RS applications, Apache Shiro, or REST fundamentals? Take a look at these posts: Page 15 JSON Web Tokens (JWTs) are so hot right now. They're all the rage in web development: Trendy? using JWTs. Specifically, why it's a bad idea to use JWTs as session tokens for most people. What are JWTs? If you aren't that complicated! The way I like to think of JWTs is that they're just some JSON data that you can verify came from someone you know. Pretend I'm blind and hard of hearing. Let's also pretend that last week you bought me lunch, and now I need your Venmo address to pay you back. If I ask you for your Venmo address, I might accidentally send them the money I owe you. That's because I heard someone shout a Venmo address, and I trusted that it was you, even though in this case, it wasn't. JWTs were designed to prevent this sort of thing from happening. JWTs give people an easy way to pass data between each other, while at the same time verifying who created the data in the first place. So, going back to our previous example, if I received 1,000,000 different JWTs that contained a Venmo address, I'd easily be able to tell which one actually came from you. How do JWTs Work? JWTs are JSON data, encoded as a string, and cryptographically signed. I know that sounds fancy, but it really isn't. The core of any JWT is claims. Claims are the JSON data inside the JWT. It's the data you care about, and want to pass along securely to someone else. I'm not going into the details here, but just know that JWTs hold JSON data. How do JWTs make it so that you know whether or not they can be trusted? Cryptographic signatures. Let's say I write a letter. When I sign that letter, I'm "signing" it. This means that anyone who reads that letter will know that I wrote it. And, because my signature is unique, there will be no question of its autienticity. Using symmetric region is and provide the same way. There are two main ways to sign jwis arent magic-they rejust blobs of JSON that have been cryptographically signed. Regardless of whether they're symmetrically signed, they provide the same guarantees: you can trust that a JWT is valid and created by someone you have faith in. These properties of JWTs make them really useful in certain scenarios where you need to assert that some data can be trusted (such as when using federated login/single sign-on). JWT Encryption Note One final note I want to make about JWTs before moving on: their contents (the JSON data inside the JWT, even without a key. JWTs don't try to encrypt your data so nobody else can see it, they simply help you verify that it was created by someone you trust. Now, if you do want to encrypt your JWTs you can do so by using JWTs and need encryption, be sure you use the right thing! How are People Using JWTs Today? The most common use case for JWTs is authentication. There are tons of web security libraries which use JWTs as session tokens, API tokens, etc. The idea is that when someone authenticates to a website/API, the server will generate a JWT that contains the user's ID, as well as some other critical information, and then send it to the browser/API/etc. to store as a session token. When that user visits another page on the website, for instance, their browser will automatically send that JWT to the server, which will validate the JWT to make sure that it's the same token it created originally, then let the user do stuff. In theory, this sounds nice because: When the server receives a JWT, it can validate that it is legitimate and trust that the user is whoever the token says they are The server can validate this token locally without making any network requests, talking to a database, etc. This can potentially make session management faster because instead of needing to load the user from a database, etc. people like using JWTs: they are stateless. These two perks sound great because they will speed up webapp performance, reduce load on cache servers, and generally provide faster experiences. As a bonus benefit, as the webapp creator you can embed other information about the user into your JWT: User permissions User personal information Etc. This means that you can reduce your database load even further by simply embedding extra user information in your tokens as well! Why Do JWTs are used for authentication purposes, let's get into my favorite subject of all: why JWTs are not good session tokens. I often argue with coworkers, colleagues, and friends about this, so it's nice to finally get all my thoughts on the subject down in bytes. In particular, I plan to explain to you why normal old sessions are superior to JWTs in almost every way. Context Before I start making web developers all over the world angry, I want to provide some context into my reasoning. Most websites that developers build are relatively simple: A user registers for the website A user clicks around and does stuff The website a user's information 10,99% of all websites match the criteria above. For these types of websites, what's important to know is that almost every page a user interacts with contains some sort of dynamic data. Odds are, if you're running a website that requires a user to sign in to use it, you're going to be doing things with that user in your database often: Recording the actions a user is taking Adding some data for the user to the database Checking a user's permissions to see if they can do something Etc. The important thing to remember is that most sites require user information for nearly every operation. With that out of the way, let's get into the reasons why JWTs suck. First up? Size. Size Let's take a look at two scenarios: Storing a user ID (abc123) in a JWT If we store the ID in a cookie, our total size is 6 bytes. If we store the ID in a JWT (with basic header fields set, as well as a reasonably long secret), the size has now inflated to 304 bytes. For storing a simple user session, that is a ~51x size inflation on every single page request in exchange for cryptographic signing (as well as some header metadata). For reference, here were the JWT claims I used to get that number: { "iss": " ", "sub": "abc123", "nbf": 1497934977, "exp": 1497934977, "jti": "1234567", "typ": "authtoken" } Let's say that your website gets roughly 100k page views per month. That means you'd be consuming an additional ~24MB of bandwidth each month. That doesn't sound like a lot, but when you're consistently bloating every single page request, all the little things start to add up. Also: this example was using the smallest possible amount of information in JWTs than just a user ID, greatly increasing these byte counts. You're Going to Hit the Database Anyway As I mentioned above, most websites that require user login are primarily generating dynamic user content for CRUD operations (create, update, delete). The issue with using JWTs on these websites is that for almost every single page the user loads, the user object needs to be loaded from a cache / database because one of the following situations are occurring: A mission critical user check needs to run (eg: does this user have enough money in their account to complete the transaction?) A database write needs to occur to persist information is related to the user, it's likely that the full user object must also be retrieved from the database) The full user object must be pulled out of the cache / database so that the website can properly generate its dynamic page content Think about the websites you build. Do they often manipulate user data? Do they frequently use various fields on the user account to work? If so, your site falls into this category, and you'll likely be talking to the cache server / database regardless of whether or not you've got a JWT. This means that on most websites, the stateless benefits of a JWT are not being taken advantage of. To compound this issue, since JWTs are larger (in bytes) and also require CPU to compute cryptographic signatures, they're actually significantly slower than traditional sessions when used in this manner. Almost every web framework loads the user on every incoming request. This includes frameworks like Django, Rails, Express.js (if you're using an authentication library), etc. This means that even for sites that are primarily stateless, the web framework you're using an authentication library), etc. This means that even for sites that are primarily stateless, the web framework you're using is still loading the user object regardless. Finally: if you're storing your user information in modern cache like memcached/redis, it's not uncommon over a VPC to achieve cache GET times of 5ms or below, which is extremely fast. I've personally used DynamoDB on Amazon in the past as a session store, and consistently achieved 1ms cache retrieval times. Because caching systems are so fast, there's very little performance overhead when retrieving users in this manner. Redundant Signing One of the main selling points of JWTs are cryptographic signatures. Because JWTs are cryptographic signatures. Because JWTs are cryptographically signed, a receiving party can verify that the JWT is valid, and trusted. But... what would you say if I told you that in pretty much every single web framework created over the last 20 years, you could also get the benefits of cryptographic signatures when using JWTs themselves. In fact, in most web frameworks cryptographically sign (and many encrypt!) your cookies for you automatically. This
means that you get the exact same benefits as using JWTs themselves. In fact, in most web authentication cases, the JWT data is stored in a session cookie anyways, meaning that there are now two levels of signing. One on the cookie itself, and one on the JWT. While having two levels of signing may sound like a good idea, it is not. You get no security benefits, and you've now got to spend twice as long on CPU cycles to validate both signatures. Not really ideal for web environments where milliseconds are important. This is especially true in single threaded environments (cough cough nodejs) where number crunching can block your main event loop. What's a Better Solution? If JWTs suck, then what's a better solution? If jwTs suck, then what's a better solution? ones described above, then your best bet is to stick with boring, simple, and secure server side sessions. Instead of storing a UWT inside of a cookie and be done with it. If your website is popular and has many users, cache your sessions in a backend like memcached or redis, and you can easily scale your service with very little hassle. Excellent quality web frameworks like Django know this, which is why they operate this way. How Should I Use JWTs? It's important to note that I don't hate JWTs. I just think they're useless for a majority of websites. With that said, however, there are several cases in which JWTs can be useful. If you're building API services that need to support server-to-server (like a mobile app or single page app (SPA)) communication, using JWTs as your API tokens is a very smart idea. In this scenario: You will have an authentication API which clients authenticate against, and get back a JWT Clients then use this JWT to send authenticated requests to other API services use the client's JWT to validate the client is trusted and can perform a network validation For these types of API services, JWTs make perfect sense because clients will be making requests frequently, with limited scope, and usually authentication data can be persisted in a stateless way without too much dependence on user data. If you're building any type of service where you need three or more parties involved in a request, JWTs can also be useful. In this case the requesting party will have a token to prove their identity, and can forward it to the third (or 4th ... nth) service without needing to incur a real-time validation each and every time. Finally: if you're using user federated user protocols Wrap Up When you start building your next website, just rely on your web framework's default authentication libraries and tools, and stop trying to shove JWTs into the mix unnecessarily. Finally, if you're interested in web security and all sorts of other interesting problems in the authentication space, you should consider signing up for an Okta Developer Account. Our API service stores user accounts for your web apps, mobile apps, and API services, and makes web security site where we publish lots of stuff like this. If you have any questions, feel free to hit me up on Twitter @rdegges. Page 16 Okta is investing heavily into making developers successful by creating great developers everything they need to build modern, secure applications. But equally important is how Okta speaks to developers. How we engage with the community and build our reputation with a wide range of developers. At the heart of that effort, is our Developer Relations (DevRel) team. In this post, we'd like to introduce you to that team and give you a behind the scenes glimpse into how a large, successful company builds an authentic, high-value developer relations program from scratch. How to Build a Developer Relations Team Building a developer relations team at Okta was easy. Stormpath already had a DevRel team at Stormpath wasn't easy. The process started by hiring developers that could create and maintain SDKs for Stormpath's API. Once the SDKs were created, these same developers started advocating for their respective projects through blog posts and speaking engagements. Ultimately, this meant finding people who were a special combination of great developers with great taste for a good developer experience, who also genuinely loved helping other people build stuff, and were already actively engaged with the developer community because they loved it. So, who made the team? Meet the Okta DevRel Team The DevRel team at Okta is made up of four individual contributors, each with our specialties. Let me take a moment and introduce them to you. Randall Degges Randall is our Lead Developer Advocate. He wrote the first book on Heroku, loves to hack Python and JavaScript, and is our go-to guy when it comes to deployment pipelines and AWS. If you're having issues with Okta's Python or Node. SDKs, Randall's the guy to talk to. Nate Barbettini Nate specializes in full-stack .NET and JavaScript. He was recently granted the .NET MVP Award from Microsoft for his contributions to the .NET community. If you're having issues with our .NET SDK, talk to Nate. Lee Brandt Lee also specializes in .NET and JavaScript. He's a long-time Microsoft MVP and the founder of KCDC (Kansas City Developers Conference). KCDC is one of the region's largest developer conferences and has numerous languages and communities represented. Lee is a rockstar in .NET, Angular, and React, so hit him up if you have issues with these frameworks and Okta. Matt Raible and I started as a web developer, then a Java Champion and like to code in both Java and JavaScript, though TypeScript has been a lot of fun lately. If you're having issues with our Java SDK, Spring Boot, our Sign-In Widget, or anything Angular, let me know! Why Developer Relations? We have a Developer Relations? We have a Developer Relations? the past, companies that sell software could sell it via marketing, using a top-down approach that targeted CEOs or CTOs. Some companies still sell software this way, but the market has changed and developers have become the dominate decision makers. proof? See Stephen O'Grady's The New Kingmakers. While the actual number might be up for debate, the importance of technical talent is not. The most successful companies - virtually every company today are those that understand the strategic role that developers will play in their successful technology companies - virtually every company today. needs a developer strategy. There's a reason that ESPN and Sears have rolled out API programs, that companies are being bought not for their products but their produ on the Okta SDKs, coding new examples to show how certain frameworks interact with our API, and hacking because we like to hack! We know that developers are the decision makers because we've been influencing software decisions for most of our lives. Marketing to developers are the decision makers because we like to hack! We know that developers are the decision makers because we like to hack the decision makers because we've been influencing software decisions for most of our lives. organization. Proven tactics like branded collateral, Gartner and Forrester research, hosted events, and press releases can be difficult to map to developers want to use technology that'll keep them excited and employed. Developers listen to the community. If there are negative things said about your product or API, you're going to have a hard time winning them over. DevRel means engaging the community. It's a focused type of field marketing for the purpose of awareness, evaluation, sentiment, and product feedback. Our job is to make other developers aware that we exist and respectful of our opinions and thoughts via blog posts, speaking at conferences, and creating cool shit. How DevRel Works at Okta We plan to increase awareness of Okta's Identity Platform for Developers) with many initiatives. Developer content marketing and thought leadership Regional community presence Influencer programs Support and engagement in open source tooling Internal advocacy Developer content marketing and thought leadership Okta's Developer Blog is our primary way of creating content and providing thought leadership. We're on Twitter @OktaDev, and chances are you'll find one of us speaking at your favorite tech conference. We recognize that content is king and we use our blog posts to extend our reach into the communities we know devs are already participating in. Image created by Chris Kelly / @amateurhuman We do this so we can share the interesting stuff that we're building. It's a win-win situation

and helps both us and our users. Regional community presence For those developers that allows us to buy developers a company-wide initiative that allows us to buy developers a strong cup of coffee or an ice cold beer. In exchange, we hope to hear about your pain points with APIs like ours, and how we can make things easier for you. Our DevRel Team is traveling to many big cities in the US to give tech talks, hang out, and generally get to know YOU. We do this so we can solicit feedback from other developers, build relationships, and try to positively impact developers lives all over the place. If you're interested in having us speak at your user group outside of the US, we can make that happen too! However, at this time, we require you to cover our travel expenses. We sponsor meetups because we recognize that they're an important source of knowledge for many developers around the world. They also offer a sense of community, networking, and social interaction that can't be found online. Influencer programs We're just getting started with our influencer program. We hope to engage with influencer programs We're just getting started with our influencer program. We hope to engage with influencer program. We hope to engage with influencer programs We're just getting started with our influencer program. example, giving them rides from the airport, taking them out to dinner, and hosting community meetups. If you're an influencers are and how traveling solo can be lonely. We want to make your hard work and traveling experience more pleasant! Support and engagement in open source tooling Supporting open source is something we did well at Stormpath. We helped support the Java JWT project, created a plugin for Chrome to inspect JWTs, and actively engaged with the open source security project security project. Okta, we plan to do much of the same. We're working to make better, and we plan to do the same for OpenID Connect. We'll continue to invest in the Java JWT project, and we're working closely with the Spring Security team to make sure their OpenID Connect. We'll continue to invest in the Java JWT project that helps developers use OAuth, OIDC, and other authentication standards, let us know how we can help! We have the budget to help with hosting costs, promotional materials, or whatever your project might need. Internal advocacy We're doing our best to educate Okta employees how to work with developers too. We've already done several presentations on what DevRel is, and we're making moves to make our documentation better, and our blog friendlier. We know that Developer DNA cannot just be a part of the DevRel team. All of Okta needs Developer DNA. We've been telling people they can help by sharing feedback with us, having a beer with an engineer, build for good developer experience, and by giving back to the community. DevEx, DevRel, and ROI The DevRel Team focuses on making developers' lives easier, but it's not all fun and games. Our fearless leader, Alex Salazar, is in charge of making sure our efforts are right on the business side of things. Alex is the former CEO of Stormpath, so he's hyper aware of revenue growth, cost reduction, and trying to balance predictability and risk. He knows that our go-to-market strategy needs to be around developer relations (DevRel). It's going to be tough to market to developers if our product is crap. We're focused as a team on cost efficiency and repeatability, to increase our ROI. We know what to developer relations (DevRel). It's going to be tough to market to developer sif our product is crap. We're focused as a team on cost efficiency and repeatability, to increase our ROI. We know what to developer relations (DevRel). types of DevRel are the most effective (blogging, how to videos). We know what DevEx investments will have the greatest impact (ease of use, excellent documentation). We'll do more of what's working, and stop doing the things that aren't. And more than anything, we're tracking the metrics that matter. This way, we know how many developers are using our API, with which SDKs, and how long it takes them to activate their account after signing up. Here's to the Future! Being a part of something that's just beginning, with a team of outstanding individuals. If you're a developer using Okta, and you have feedback to share, please contact us at developers@okta.com. DevRel at Okta is a fun ride, and we're just getting started. If you'd like to talk to me about DevRel at Okta, or in your organization, please hit me up on Twitter @mraible or directly via email to matt.raible@okta.com. Page 17 With Okta and OpenID Connect (OIDC) you can easily integrate authentication into an Ionic application, and never have to build it yourself again. OIDC allows you to authenticate directly against the Okta API, and this article shows you how to log in with OIDC redirect, using Okta's Auth SDK as well as how to use OAuth with Cordova's in-app browser; user registration is omitted as the feature is still under active development. Why Ionic? Ionic is an open source mobile SDK for developing native web applications. It leverages Angular and Apache Cordova to allow you to build mobile apps with HTML, CSS, and JavaScript. Apache Cordova to allow you to build mobile apps with HTML code inside a native WebView on the device, using a foreign function interface to access the native resources of it. You might've heard of PhoneGap - this is Adobe's commercial version of Cordova. Cordova and PhoneGap allow you to target multiple platforms (e.g. Android and iOS) with one codebase. Not only that, but the apps look like native apps and perform just as well. If your appeared of PhoneGap allow you to target multiple platforms (e.g. Android and iOS) with one codebase. Not only that, but the apps look like native apps and perform just as well. If your appeared of PhoneGap allow you to target multiple platforms (e.g. Android and iOS) with one codebase. need to tap into native features that aren't available in web technologies, there are a number of native plugins. I first started using Ionic in late 2013. The project I was working on was developing a native application, but wanted to build several screens of the application with HTML so web developers could author them. I wrote about my experience in March 2014. I enjoyed working with it and found that porting an existing app to use it was more about modifying HTML and tweaking CSS. Ionic 2 was released in January, making it possible to develop Ionic applications with Angular. 4. NOTE: "Angular" is the common name for Angular 2+. AngularJS is the common name for AngularJS for more information. This article will show you how to build a simple Ionic application and add user authentication to it. Most applications require authentication, so they know who the user is. Once an app knows who you are, it can save your data and better personalization features. Get Started with Ionic, complete the following steps: Install Ionic and Cordova using npm: npm install -g cordova ionic Create an Ionic Application From a terminal window, create a new application using the following command: You will be prompted to integrate your app with Cordova, answer yes. When prompted to install the free Ionic Pro SDK and connect your app, answer no. Project creation may take a minute or two to complete, depending on your internet connection speed. Run the commands below to start your Ionic application. cd ionic-auth ionic serve This command will open your default browser on . You can use Chrome's device toolbar to see what the application will look like on an iPhone 6. One slick feature of Ionic's serve command is it shows compilation errors in the browser, rather than in the (sometimes hidden) developer console. For example, if you give an invalid type to the rootPage variable in app.component.ts, you'll see an error like the one below. Add User Authentication Ionic Cloud offers a free Auth service. It allows authentication with an email and password, as well as social providers like Facebook, Google, and Twitter. It provides several classes you can use to build authentication, but it "requires your own server to handle authentication" and will be decommissioned on January 31, 2018. While there are a few from last year. You might notice that both tutorials require quite a bit of code. Also, there doesn't seem to be a lot of documentation on how you can verify user credentials from the Auth service in a backend service. Create an OpenID Connect App in Okta OpenID Connect (OIDC) builds on top of the OAuth 2.0 protocol. It allows clients to verify the identity of the user and obtain their basic profile information. To integrate Okta's Identity Platform for user authentication, you'll first need to: Register and create an OIDC application Log in to your Okta account and navigate to Application Select SPA and click Next Give your application a name (e.g. "Ionic OIDC") Change the Base URI and Login redirect URI to and click Done. You should see settings like the following: Create a Login Page Generate a login page for authentication by running the following command: In the generated src/pages/login/login.html, add a form with username and password fields. Login {{error}} Login You can leverage a couple of open source libraries to perform the actual authentication. The first one is Manfred Steyer's angular-oauth2-oidc. This library allows you to interact with identity and access tokens easily. The second is the Okta Auth SDK. OAuth is not an authentication protocol, but OIDC is. Why issue to interact with identity and access tokens easily. it necessary to add Okta's authentication library then? Because OIDC authentication works via redirect (when using in a SPA) and I'd rather perform authentication without redirecting to Okta. Install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using npm. npm install angular-oauth2-oidc and the Okta Auth SDK using np basic structure of the LoginPage class and a constructor that configures your OIDC settings with the OAuthService from angular-coauth2-oidc. You will need to replace {clientId} with the ClientID from your Okta OIDC settings and {yourOktaDomain} with your account's correct URI. import { Component, ViewChild } from '@angular/core'; import { clientID from your Okta OIDC settings and {yourOktaDomain} with your account's correct URI. IonicPage, NavController } from 'ionic-angular'; import { JwksValidationHandler, OAuthService } from 'angular-oauth2-oidc'; @IonicPage() @Component({ selector: 'page-login', templateUrl: 'login.html' }) export class LoginPage { @ViewChild('email') email: any; private username: string; private error: string; private error: string; private error: string; private error: string; private username: string; private error: string; private e constructor(private navCtrl: NavController, private oauthService.clientId = '{clientId}'; oauthService.clientId = '{clientId}'; oauthService.clientId = '{clientId}'; oauthService.clientId = 'authService.clientId = 'authService.clientId'; oauthService.clientId = 'authService.clientId'; oauthService.clientId'; oauthService.clientId = 'authService.clientId'; oauthService.clientId'; oauthSer  $JwksValidationHandler(); // Load DiscoveryDocument().then(() => \{ this.email.setFocus(); \}, 500); \} \}$  Modify src/app/app.component.ts to check to see if the user this.oauthService.loadDiscoveryDocument().then(() => { this.email.setFocus(); }, 500); } } LoginPage as the rootPage. import { Component } from '@ionic-native/splash-screen'; import { TabsPage } from '../pages/tabs/tabs'; import { OAuthService } from 'angular-oauth2-oidc'; import { DauthService } from 'angular' import { DauthService } from 'angular-oauth2-oidc'; import { DauthService } from 'angular' import } from 'angular' from '../pages/login/login'; @Component({ templateUrl: 'app.html' }) export class MyApp { rootPage: any = TabsPage; constructor(platform: Platform, statusBar: Status platform.ready().then(() => { statusBar.styleDefault(); splashScreen.hide(); }); } } Update src/app/app.module.ts to add OAuthModule, HttpClientModule, Http LoginPageModule, OAuthModule.forRoot(), IonicModule.forRoot(MyApp) ], ... }) Run ionic serve to make sure the LoginPage is displayed when the app first loads. You'll see the following error when the app tries to load: No provider for HttpClient! This error happens because OAuthService has a dependency on Angular's Http, but it hasn't been imported into your project. Add HttpModule as an import in src/app/app.module.ts. import { HttpClientModule } from '@angular/common/http'; @NgModule({ ... }), ... }) Now the login screen should load. You can use Chrome's Device Toolbar to see what it'll look like on an iPhone 6. Add a login() method in src/app/pages/login/login.ts that uses the Okta Auth SDK to 1) login and 2) exchange the session token for an identity and access token. An ID token is similar to an identity card, in standard JWT format, signed by the OpenID Provider. Access token are part of the OAuth specification. An access token can be a JWT. They are used to access protected resources, often by setting them as an Authentication header when making a request. import \* as OktaAuth from '@okta/okta-auth-js'; import { Tabs/tabs'; ... login(): void { this.oauthService.createAndSaveNonce().then(nonce => { const authClient = new OktaAuth({ clientId: this.oauthService.createAndSaveNonce().then(nonce => { const authClient = new OktaAuth({ clientId: this.oauthService.clientId, redirectUri: this.oauthService.redirectUri, url: 'https://{yourOktaDomain}', issuer: 'default' }); return authClient.signIn({ username: this.username, password }).then((response) => { if (response.status === 'SUCCESS') { return authClient.token.getWithoutPrompt({ nonce: nonce, responseType: ['id token', 'token'], sessionToken: response.sessionToken, scopes: this.oauthService.scope.split(') }).then((tokens) => { const idToken = tokens[0].idToken; const keyValuePair = `#id token=\${encodeURIComponent(idToken)}`; this.oauthService.tryLogin({ customHashFragment keyValuePair, disableOAuth2StateCheck: true }); }); } else { throw new Error('We cannot handle the ' + response.status + ' status'); }); } You want an identity token so you can have more information about the user. You want an access token so you can use it to access protected APIs that require a Bearer token. For example, in Adding Authentication to Your Angular PWA, there's a BeerService that sends an access token when it makes an API request. import { Injectable } from '@angular/core'; import { Http, Response, Headers, RequestOptions } from '@angular/http'; import { 'rxjs/add/operator/map'; import { Observable } from 'rxjs'; import { OAuthService } from 'angular-oauth2-oidc'; @Injectable() export class BeerService { constructor(private http: Http, private oauthService) { } getAll(): Observable { const headers: Headers = new Headers(); headers.append('Authorization', observable } from 'rxjs'; import { OAuthService } from 'angular-oauth2-oidc'; @Injectable() export class BeerService { constructor(private http: Http, private oauthService) { } getAll(): Observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const headers: Headers = new Headers(); headers.append('Authorization', observable { const head this.oauthService.authorizationHeader()); let options = new RequestOptions({ headers: headers }); return this.http.get(', options) .map((response: Response) => response.json()); } You can (optionally), pretty up the login screen by adding a logo above the form. Download this image, copy it to src/assets/imgs/okta.png, and add the following above the tag in login.html. You might want to edit the image so it's only 300 pixels wide. This reduces its size to 12 KB instead of 110 KB. When you sign in, there's not much proof on the UI. Add a "Logout" button in the top right corner of the home screen. Replace the in src/pages/home/home.html with the HTML below. Home Logout In src/pages/home/home.ts, add a logout() method, as well as methods to get a name and claims in the oIDC spec. import { Component } from '@angular/core'; import { Approx { Appr } from 'ionic-angular'; import { LoginPage } from '../login/login'; import { OAuthService } from 'angular-oauth2-oidc'; @Component({ selector: 'page-home', templateUrl: 'home.html' }) export class HomePage { constructor(public app: App, public oauthService) { } logout() { this.oauthService.logOut(true); this.app.getRootNavs() [0].setRoot(LoginPage); } get givenName() { const claims: any = this.oauthService.getIdentityClaims(); } } To display this information on the home tab, add the following HTML just after the second paragraph in src/app/home/home.html. You are logged in as: {{ givenName }} Update src/app/home/home.scss to add some CSS to make the raw JSON look a bit better. page-home { .claims { pre { color: green; } } pre { border: 1px solid silver; background: #eee; padding: 10px; } Now you should see your name and claims information displayed when you log in. You should also be able to log out and see the login screen with its logo. Deploy to a Mobile Device It's pretty cool that you're able to develop mobile apps with Ionic in your browser. However, it's nice to see the fruits of your labor and validate how awesome your app looks on a phone. It does look and behave like a native app! To see how your application will look on different devices you can run ionic serve --lab. The --lab flag opens a page in your browser that lets you see how your app will display on various devices. The LoginPage tries to auto-focus onto the email field when it loads. To auto-activate the keyboard you'll need to tell Cordova it's OK to display the keyboard without user interaction. You can do this by adding the following to config.xml in the root directory. iOS To emulate or deploy to an iOS device, you'll need a Mac and a fresh installation of Xcode. If you'd like to build iOS apps on Windows, Ionic offers an Ionic Package service. Make sure to open Xcode to complete the installation. Then run ionic cordova emulate ios to open your app in Simulator. You may encounter an error like the following: \*\* BUILD SUCCEEDED \*\* Error: Cannot read property 'replace' of undefined [ERROR] An error occurred while running cordova emulate ios (exit code 1). This is a known issue and can be solved by running the following commands: cd platforms/ios/cordova && npm install ios-sim TIP: The biggest problem I found when running the app in Simulator was that it was difficult to get the keyboard > Toggle Software Keyboard to pop up. To workaround this, I used Hardware > Keyboard to pop up. To workaround this, I used Hardware > Keyboard when running the app in Simulator was that it was difficult to get the keyboard by the keyboard b nothing happens. Open Safari and navigate to Develop > Simulator > MyApp / Login, and you'll see that eventually, an error shows up in the console. If you use the Network tab, you can see that only one network request is made (to /authn), which is different than the two requests (to /authn and /authorize) that are made when running in a browser. I believe this doesn't work when the app is packaged with Cordova because it's making a request to the server with an embedded iframe that then posts back to the current window using postMessage. It seems that Ionic/Cordova doesn't support this flow (yet). To work around this issue, you can talk directly to Okta's OAuth service using an in-app browser that's provided by Cordova. Nic Raboy shows how to do this with Facebook in Using An OAuth 2.0 Service Within An Ionic 2 Mobile App. Install the Cordova plugin add cordova-plugininappbrowser Open src/app/pages/login/login.html and wrap the with a that only shows this login form when running in a browser. Add a new that is displayed when running in a browser. Add a new that is displayed when running in a browser. methods below to facilitate logging in with OAuth. redirectLogin() { this.oktaLogin().then(success => { const idToken = success.id token; const keyValuePair = `#id\_token=\${encodeURIComponent(idToken)}`; this.oauthService.tryLogin({ customHashFragment: keyValuePair, disableOAuth2StateCheck: true }); this.navCtrl.push(TabsPage); }, (error) => { this.error = error; }); } oktaLogin(): Promise { return this.oauthService.createAndSaveNonce().then(nonce => { let state: string = Math.floor(Math.random() \* 1000000000).toString(); if (window.crypto) { const array = new Uint32Array(1); window.crypto.getRandomValues(array); state = array.join().toString(); } return new Promise((resolve, reject) => { const oauthUrl = this.buildOAuthUrl(state, nonce); const browser.addEventListener('loadstart'  $(event) => \{ if ((event.url).indexOf('') == 0) \{ browser.close(); const parsedResponseParameters[i].split('#')[1]).split('#'$ const defaultError = 'Problem authenticating with Okta'; if (parsedResponse['state'] !== state) { reject(defaultError); } else if (parsedResponse['state'] !== null) { reject(defaultEr + '&nonce=' + nonce; } Change the redirectUri that's set in the constructor to hard-code. By making it a known URL, we can look for it with the in-app browser on the "loadstart" event. constructor(private navCtrl: NavController, private oauthService: OAuthService: OAuthService of a but to re-deploy your app to your phone after making these changes. ionic cordova emulate ios Now you should be able to log in by clicking on the "Login with Okta" button and entering valid credentials. The nice thing about using this technique is the Okta login screer has Remember Me and Forgot Password support, so you don't need to code those yourself. To deploy the app and run it on your device. This commands to build the app and run it on your device. This commands to build the app and run it on your device. "MyApp" requires a development team. Select a development team in the project editor. Code signing is required for product type 'Application' in SDK 'iOS 10.3' Open your project in Xcode using the command below. open platforms/ios/MyApp.xcodeproj Ionic's deployment team. the target in Xcode and click the play button to run your app. The first time you do this, Xcode may spin for a while with a "Processing symbol files" message at the top. Once you've configured your phone, computer, and Apple ID, you should be able to open the app and log in. Below is how it looks on my iPhone. Android To emulate or deploy to an Android device, you'll first need to install Android Studio. As part of the installed the Android Studio. As part of the installed the Android Studio. To deploy to the Android emulator, run ionic cordova emulate android. This command will install Android support and display an error if you don't have any AVD (Android Virtual Device) images. (node:9300) UnhandledPromiseRejectionWarning: CordovaError: No emulator images (avds) found. 1. Download desired System Image by running: /Users/mraible/Library/Android/sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android avd HINT: For a faster emulator, use an Intel System Image and install the HAXM device driver To create a new AVD, open Android /sdk/tools/android /sdk/tool and click Play. I chose a Pixel 2. After performing these steps, you should be able to run ionic cordova emulate android and see your app running in the AVD. NOTE: If you get an application error that says "The connection to the server was unsuccessful. (file:///android/www/index.html)", add the following line to config.xml. This line sets the default timeout to 60 seconds (default is 20). Thanks to the Stack Overflow community for this solution. PWAs with Ionic Ionic app as a web app (rather than a mobile app) and make it run offline in browsers that support service workers. You can see how to enable service workers and make your app into a PWA is a web application that can be "installed" on your system. It works offline when you don't have an internet connection, leveraging data cached during your last interactions with the app. Adding PWA features can make your apps load a lot faster, creating happy users. To learn more about PWAs, see The Ultimate Guide to Progressive Web Applications. Ionic has invested heavily in supporting PWAs. You can read more about why in What Progressive Web Applications. Ionic has invested heavily in supporting PWAs. You can read more about why in What Progressive Web Applications. like how Ionic takes your web development skills up a notch and allows you to create mobile applications that look and behave natively and perform swiftly. You can see the complete source code for this project on GitHub. Please contact me on Twitter @mraible or on Okta's Development skills up a notch and allows you to create mobile applications that look and behave natively and perform swiftly. Angular, or Okta, please see the following resources: Page 18 Development and work more efficiently, sometimes this also means looking for new libraries or processes (or more often less process). For many teams managing authentication and access control for their apps and APIs is more work than it's worth, or simply not an efficient use of time, so we want to share a few tips that will save you time and code, along with making your applications more secure and easie to maintain. For a bit of context: Okta at its core, is a Java-based REST+JSON API, built on the Spring Framework. We store user credentials and data on behalf of other companies, so for us security is paramount. Thus, my first requirement for these tips is that they help manage access to your Java API securely. These tips should be universal to any type of Java application. They will help you move faster, write less code, and at the same time be more secure: a trifecta! 1. Don't roll your own security stack is no different, and the risk/reward just isn't worth it. There's a high chance you'll make some sort of mistake. Since 1999 there have been 89373 CVEs (Common Vulnerabilities and Exposures). And that's just what's been made public, many of those by very smart people. You may think that dealing with a simple use case like validating a user's password is trivial, all you're doing is just comparing a couple strings after all. You would be wrong. You need to validate the password's hash, audit the attempt, mitigate against dictionary attacks, and that's just the tip of the iceberg. Your best bet is to use an existing library or a framework like Apache Shiro or Spring Security and let the framework handle the complexities! 2. Use TLS, always! It's 2017, everything should be HTTPS now, even the sites on your company's intranet. Let's encrypt makes this free and easy, which means you can stop using instance with a certificate. Making your application require TLS (HTTPS/SSL) is usually a one liner, so everybody should be doing it! For Apache Shiro, it is just property: And Spring Security, a single method call when configuring an HttpSecurity: http:requiresSecure(); Or just use a few properties with Spring Boot: server.ssl.key-store=classpath:keystore=c secret 3. Build your Java web service with Spring Boot is an opinionated view of the Spring platform which makes it dead simple to write twelve-factor apps in very few lines. If you're still building WAR files you owe it to yourself to check this out. You can create complicated, application wide functions like setting up an OAuth resource server by using a single annotation (@EnableResourceServer) or change the server's port with a single property: If Spring is not your back It's pretty difficult to pinpoint errors without any data. Spring Boot makes gathering metrics easy with Actuator, just add a single dependency to your application. org.springframework.boot spring-boot-starter-actuator Then browse to /health checks or application's /metrics endpoint, out of the box: { "classes": 7704, "classes.loaded": 7704, "classes.unloaded": 0, "counter.status.200.metrics": 1, "gc.ps marksweep.count": 2, "gc.ps mar "httpsessions.active": 0, "httpsessions.max": -1, "instance.uptime": 25020, "mem": 529086, "mem.free": 262222, "nonheap.committed": 556103515625, "threads.daemon": 22, "threads.daemon": 22, "threads.totalStarted": 32, "threads "uptime": 37182 } 5. Protect your sensitive bits People treat API keys in a file, make sure there is limited around or checked into source control. Maybe this is because they seem more opaque than a password, I don't know, but they're just as sensitive, if not more so. If you need to store your API keys in a file, make sure there is limited access to that file. For example, we recommend storing our Okta vaml file in private directory ~/.okta/okta.vaml and setting API keys for users of your applications, plan to warn them. SSH ignores files in your ~/.ssh directory if the permissions are not set correctly. GitHub does a great job of warning users by marking items in the UI with 'Danger Zone' marking. Bonus: Write less code, give Okta a try! Java has a bit of a reputation (and rightly so) for being verbose. All of the examples above show you how to write less code and when possible take advantage of existing libraries so you can focus on the code that will drive your business. Shameless plug time: You can also write less code by integrating Okta for fully featured user management. Just connect your apps, choose an IdP (or use ours), add users, configure rules, customize your login page, and then gain insights from our built-in reports. Want to see Okta in action? Check out these tutorials: And, as always, if you have any questions or comments you can hit me up on Twitter @briandemers, or follow our whole team @oktadev. Page 19 Creating a consistent environment for development, testing, staging, and production is one of the big benefits of using containers. Not only do containers make the entire environment portable, they remove environment-specific problems, like, "Why does it work in test, but not in production?" Usually, it's a package or framework that's installed on the test machine that is not on the production?" Usually, it's a package or framework that's installed on the test machine that is not on the production?" consistent container, you need an image that is configured in code that can be versioned and distributed. That's where the Dockerfile (without an extension) is simply a text file with some keywords and rules that all have the same set up. In this tutorial, you'll build a Dockerfile that you can use to create an image for a basic web application. In the previous article in this series, I told you that images are like blueprints for creating containers. Well really, they are containers. Well really, they are containers frozen in time that you can use to "stamp out a copy" anytime you want. To get the base application, just clone it from: GitHub. This is just a basic Node website. Don't have Node installed on your machine, you're not even going to run it in a container. Start with a Base Docker Image Most of the time, you won't start from scratch. You will create a Docker image based on another Docker image. The FROM line tells Docker what base image you want to use to build your new image. This must be the first line of the Dockerfile, you can have comments above it, but no other commands. In this case, you'll be starting from the official node:8.4 image. So create a file called Dockerfile in the root folder of the application and add the FROM line right at the top: This tells Docker that we want to start from the official Node and NPM to the image. Get your Node App into the Image Next, you'll run some commands to get your app (and it's dependencies) into the image you're creating. This COPY command just copies everything from the current directory (since your Dockerfile is in the root folder of your node application) to a folder called /app inside the image you're creating. Next, you'll set the working directory in the Dockerfile. This tells Docker that the rest of the commands will be run in the context of the /app folder inside the image. Next, you'll add a RUN command to get the application's dependencies: You might be thinking, "That's a really weird way to run things!" This style of RUN command in a Dockerfile is called the "exec form". You can write these commands in "shell form", like so: Use the exec form to avoid the image's shell munging string arguments. If your shell command relies on a specific shell and you are not sure if the shell form command will run in. Overall, this command will restore all the NPM packages for your project. Expose and Run Your Node App Next, you'll open up port 3000 on TCP (where our app runs), to the outside world. Lastly, you'll run the application, so when building this container it is only natural that we have a command that we want to run that will get our application. running in the container. To do this, we need to run a CMD command. Whatever is running, the container is running, the container is running, the container is running. You could also use the ENTRYPOINT command in the Dockerfile, but either work and you will see the ENTRYPOINT command in the next post on docker-compose. Your whole Dockerfile is six lines long. The FROM line starts from a base image that gives you most of what you need, then copies your code to the image and runs a few commands to get dependencies and compile the app. Then opens port 5000 to listen for requests. Meet Your Dockerfile The finished Dockerfile: FROM node:8.4 COPY . /app WORKDIR /app RUN ["npm", "install"] EXPOSE 3000/tcp CMD ["npm", "install"] EXPOSE 30 build -t tutorial:0.0.1 . Just like when pulling images from Dockerhub, this command tells the Docker engine to create a repository named "tutorial" and tag it with "0.0.1". When it's finished, you can run: You'll see the image in your list named tutorial with a tag of 0.0.1. If you want to create a container from this image and run it, run the command: docker run -p 3000:3000 -d --name demo tutorial:0.0.1 This will create a container based on the tutorial:0.0.1 image that you want to run it in daemon mode (in the background). Finally, it also has the -p switch that maps port 3000 on the host machine (your local machine) to the exposed port on the container (formatted like [host port]: [container port]). This will allow you to go to on your machine and be viewing the container from a base image and added your application to it! As you can see, it's easy to put together a container when you find the right base image to build from. Obviously, there are a lot of other things the Dockerfile can do for you. To find out more about what you can do in a Dockerfile check out the documentation. Now that you're ready to start composing containers and delivering those containers to production! If you have any questions, comments, or suggestions, feel free to reach out to me via email, or hit me up in the comments or via Twitter @leebrandt. Page 20 I'm genuinely excited to announce that today, we're officially re-launching the new and improved Okta Identity Platform. Everything has been molded to our vision, and we're aiming to do something we could not before: build the world's largest authentication-as-a-service platform for developers of all shapes and sizes. The new Okta Identity Platform is our attempt to make authentication and authorization problems a relic of the past. We want to provide beautiful developer libraries across every programming language and framework to make adding things like... User registration User login Password reset Social login Single Sign-On API authentication, best practices, etc. If you use one of our new developer libraries, we'll do our very best to solve all your user management problems. While the Okta service isn't perfect, and certainly has some rough edges, it's something we're all incredibly passionate about, and working hard every single day to improve. It will get better. We won't be satisfied until Okta fills the void that exists in the web world right now, and provides the absolute best platform for developers of all different types to scratch their user management itch. This means we're building the service to cater to actual developers of all types: students, hobbyists, 10pm - 4am hackers (like myself), startups, and even large enterprises. We're aiming to build an extremely low-cost, usagebased service that anyone can use without the need to commit to expensive plans and upsells. We want to make something that WE would want to use in our next passion project. For applications with more active users than that, we've got inexpensive usage-based plans. We'll be doing our absolute best to build something that we hope you will love as well. If you're interested in trying out the new Okta Identity Platform that we've been working on, please sign up today and hit us up if you've got questions, comments, or feedback. Finally, if you'd like to read along with the entire story of how we got here, you can read my personal thoughts on the subject.
